

DIAGNOSTIC CONFIGURATOR

reference manual

For HP 2114, 2115, 2116, 2100, and HP 1000 M-, E-, and F-Series Computer Systems using the HP 24396A through HP 24396F Diagnostics on Multimedia or the HP 24998-14002 Diagnostic Library for the HP 1000 Computer Systems.

ABSOLUTE BINARY PROGRAM NO. 24296-60001
DATE CODE 1928

PRINTING HISTORY

The Printing History below identifies the Edition of this Manual and any Updates that are included. Periodically, Update packages are distributed which contain replacement pages to be merged into the manual, including an updated copy of this Printing History page. Also, the update may contain write-in instructions.

Each reprinting of this manual will incorporate all past Updates, however, no new information will be added. Thus, the reprinted copy will be identical in content to prior printings of the same edition with its user-inserted update information. New editions of this manual will contain new information, as well as all Updates.

To determine what manual edition and update is compatible with your current software revision code, refer to the appropriate Software Numbering Catalog, Software Product Catalog, or Diagnostic Configurator Manual.

First Edition	Mar 1979	Date Code 1627.
Update 1	Jun 1979	Revised to incorporate Date Code Revisions to 1926.
Update 2	Jan 1980	Revised to incorporate Date Code Revisions to 1928.
Update 3	Mar 1980	Update 2 incorrectly specified on U1, U2, and ii as 2001 update. Changed to 1928.
Update 4	Jun 1980	Revised to incorporate Date Code Revisions to 2026.
Update 5	Oct 1980	The 9-track Mag Tape Diagnostic has been updated to Date Code Revision 2040.
Reprint	Oct 1980	Revised to incorporate Update 5.

LIST OF EFFECTIVE PAGES

The List of Effective Pages gives the most recent update number on which the technical material on any given page was altered. If a page is simply re-arranged due to a technical change on a previous page, it is not listed as a updated page. Within the manual, changes are marked with a vertical bar in the margin. When a update is incorporated in a reprinted manual, the update number and vertical bar in the margin is removed but the update number will remain on this List of Effective Pages page.

INTRODUCTION

SECTION

I

1-1. GENERAL

This manual describes the operation and use of the Diagnostic Configurator (hereafter called the Configurator), a standalone program loaded into an HP 1000 M-Series, E-Series, F-Series, 2100A/S, 2116A/B/C, 2115A, or 2114A/B Computer System* before other diagnostics. The program loads and controls the sequential execution of most of the HP 2100 Series Computer, interface, and peripheral equipment diagnostics, and they in turn reference the Configurator for certain parameters required by the diagnostics.

The Configurator is available on all diagnostic media which include paper tape, HP 7900/7905/7906 Disc, HP 7970B/E Magnetic Tape, and HP 2644/2645/48 Cartridge Tape.

The six media which carry the diagnostic library are employed to give the user a choice of several input devices. Any one of the diagnostic media listed below carries a special product number which includes the diagnostic library on the specified medium and all associated manuals:

PRODUCT NO.	MEDIUM	COMMENT
24396A	Paper Tape	} All Configurator-compatible diagnostics on any medium.
24396B	7900 Disc	
24396C	7905 Disc	
24396D	7970B Magnetic Tape	
24396E	7970E Magnetic Tape	
24396F	2644/45 Cartridge Tape	
		} All Configurator-compatible diagnostics on 7 cartridge tapes.

In addition to the 6 products mentioned above which provide all configurator compatible diagnostics on different media a special selection of diagnostics has been created. This selection (part no. 24998-14002) carries only the diagnostics which are compatible with the HP 1000 System. It consists of 6 HP 2645 cartridge tapes, and the appropriate manuals and is supplied with an HP 1000 System.

Two Diagnostic Reference Tables, which are provided in appendix A, list the Diagnostic Serial Numbers (DSN), diagnostic designations, and the associated part numbers for the HP 2100 Series diagnostics and the appropriate manuals used with the Configurator.

Table A-1 lists all the diagnostics available on the 6 media, table A-2 lists the selected diagnostics for the HP 1000 System.

The Configurator furnishes drivers (console, line printer, and diagnostic input) and commonly used utility routines for the diagnostic program. It also sets parameters related to the computer which can be referenced by the executing diagnostic. This allows a diagnostic, in conjunction with the Configurator, to test an HP 2100 Series Computer, an interface board, or a peripheral subsystem connected to the computer.

*Throughout the rest of this manual, the term "2100 Series Computer" will be used as a general reference to any one of the above-mentioned computer systems. When specifically required, the term "21MX" will be used to specify a 21MX M-Series, E-Series, or 21MX F-Series Computer.

The Configurator can be executed in three basic modes: Conversational, Automatic, and Manual. Other features in the Configurator include a Pretest (for the CPU, memory, and basic I/O), Binary Loaders, Paper Tape Dump routine, and the ability to sequentially execute diagnostics (Long Diagnostic). The Pretest is used when the CPU is in question and a check is desired prior to configurations. The Binary Loaders allow the operator to load diagnostics from any standard input device. (See paragraph 1-2d.) The Paper Tape Dump routine is used to dump (to paper tape) an absolute binary copy of the object code currently in memory. Sequential diagnostic execution capabilities are included to allow the operator to execute diagnostics in the Long Diagnostic mode from any one of the specified input devices.

It should be noted that previous diagnostics were coded for a particular computer system such as the diagnostics designed exclusively for the HP 2116 Computers. The Diagnostic Configurator is not compatible with these single computer diagnostics. However, it is possible to use the Teleprinter Driver portion of the Configurator in conjunction with previous diagnostics. Since, during the loading process, such a previous diagnostic will overlay portions of the Configurator, it is necessary to reload the Configurator when it is desired to run a newer type of diagnostic listed in appendix A. Any programs loaded with the Configurator shall not overlay the linkage area except locations 100, 105, 116, and 126 (octal). (See figure 3-2.)

Also included in this manual are the descriptions and procedures for storing the Configurator, diagnostics, and control programs on disc (Disc Initialization) and interconnecting two CPU's (Cross Link). The binary object programs are separated from the Configurator and have their own DSN's. They must be loaded prior to execution. Disc initialization is covered in appendix C, paragraph C-3 and cross link in appendix C, paragraph C-10.

1-2. REQUIRED HARDWARE

The following hardware is required:

- a. An HP 2100 Series Computer with at least 4K of memory. When a computer has more than 4K of memory, the Configurator utility routines and device drivers are relocated to the last page of memory. See paragraphs 1-5 and 2-10c for memory size restrictions. The computer must have the configured basic binary loader (BBL), for the medium on which the Configurator is stored, in the last 64 (decimal) locations in memory. (Refer to appendix E.)
- b. A loading device for the medium on which the Configurator is stored. (Normally this is the same as the diagnostic input device.)
- c. A console device, for operator communication, is optional. If a console is used, the interface must be an HP 12531B/C/D, HP 12880A, HP 12587B, HP 12966A or HP 12968A.
- d. A diagnostic input device. (The device for loading depends upon the medium on which the Configurator/diagnostic(s) are distributed or available.)
 - (1) Paper tape reader: HP 2737A/B, HP 2748A/B, HP 2758A (or teleprinter with paper tape reader).
 - (2) Magnetic tape unit: HP 7970B/E (9-track only, unit 0 only); requires DMA (DCPC).
 - (3) Cartridge disc: HP 7900A or HP 7901A (unit 0, removable platter only); requires DMA (DCPC).

- (4) Cartridge disc: HP 7905A (unit 0, removable platter and upper surface only) or 7920A (unit 0, upper surface only); requires DMA (DCPC). The disc can only be interconnected to those computers specified in the appropriate hardware manuals.
- (5) Cartridge tape: HP 2644A or 2645A Terminal; requires HP 12966A interface (strapped for external baud rate). (Operator must preselect left/right CTU. Refer to Owner's Manual, part no. 02644-90001 or 02645-90001.)
- e. A line printer (optional, only if the diagnostic requires one): HP 2767A, HP 2610A, HP 2614A, HP 2613A, HP 2617, HP 2618A, HP 2607A, HP 2778A, HP 9866A.
- f. A punch device (required for paper tape dump routine only): HP 2753A or HP 2895A.

Note: Throughout the rest of this manual, model numbers may be abbreviated for simplicity (e.g., HP 2737A/B will be simply 2737).

1-3. REQUIRED SOFTWARE

Additional software beyond the diagnostic(s) or control program(s) to be executed is not required by the Configurator. However, the operator should make sure that the diagnostic(s)/control program(s) to be run have been designed to be used with the Configurator. These programs are listed in appendix A.

1-4. TEXT CONVENTIONS USED

All halt codes, select codes, and addresses used in this manual are in octal unless specifically shown otherwise. Whenever the term "Press PRESET" is used in this manual it applies, in case of an HP 2100A/S, that "INTERNAL PRESET" as well as "EXTERNAL PRESET" has to be pressed. Throughout the flowcharts, notes, and text that follow, abbreviations may be used where necessary to conserve space and reduce confusion. The abbreviations used are listed below. (Such abbreviations as BBL, IBL, I/O, etc., are commonplace in HP 2100 Series Computer manuals and are not listed here.)

ABBREVIATION	MEANING
ADDR	Address
A-REG	A-Register
BMDL	Binary Moving Head Disc Loader
B-REG	B-Register
CART. DISC	Cartridge Disc
CR	Carriage Return
CTU	Cartridge Tape Unit
DC	Date Code
DCPC	Dual Channel Port Controller
DIAG	Diagnostic
DMA	Direct Memory Access
DRT	Diagnostic Reference Table
DSN	Diagnostic Serial Number

ENBL	Enable
EOF	End-of-File
EOM	End-of-Message
E-REG	E-Register
FWA	First Word of Available Memory
HLT(S)	Halt or halts
LF	Line Feed
LWA	Last Word of Available Memory
MAG TAPE	Magnetic Tape
MPRT	Memory Protect
M-REG	M-Register
P-REG	P-Register
REV.	Revision
RTE	Real-Time Executive
SC	Select Code
S-REG	Switch Register (or Display Register)
T-REG	T-Register (or Memory Data Register)
WCS	Writable Control Store

1-5. CONFIGURATOR LIMITATIONS

If a diagnostic, which relocates the Configurator to a different area in memory, is executed and then aborted, the restart procedures as outlined in paragraph 2-10 and figure 2-7 cannot be employed. The Configurator has to be reloaded with the binary loader and configured to continue with the execution of other diagnostics.

It is not advisable to utilize a diagnostic input device which has write capabilities (disc, magnetic tape, cartridge tape) if the functional integrity of the hardware is in question.

Due to the fact that the A-, B- and P-Register on the HP 2114A/B computer can only be accessed via the Switch Register, it is mandatory that the A-, B-, P- and S-Registers be addressed in this sequence whenever the Configurator procedure calls for updating or modifying a register. Whenever the A- and/or B-Register are modified, the P- and S-Register contents have to be restored.

On an HP 2115A/B or HP 2116A/B/C Computer, the A-, B- and P-Registers can be modified in any sequence; however, the S-Register must be the last one set.

The FPP/SIS/FFP Diagnostic (DSN 101121) cannot be executed in the automatic sequential load manner. The DSN must be specified in the A-register, and the diagnostic selection in the B-register with bit 15 of the S-register set.

The minimum memory size required is 4K. If the diagnostic to be executed or dumped on paper tape requires more than 4K, the minimum memory size is determined by the diagnostic and listed in the appropriate Diagnostic Reference Manual and in appendix A of this manual. Table A-1 lists software and manual part numbers of all diagnostics that run under control of the Configurator. If a diagnostic occupies any memory locations in the area N6300 through N6500 and the diagnostic is loaded from a disc, the available memory size is insufficient. (N= 0 for 4K, N= 1 for 8K, N= 2 for 12K, and N= 3 for 16K. If more than 16K are available, this limitation cannot be reached with any diagnostics). See also paragraph 2-10c.

If the Writable Control Store (WCS) accessory is installed, it must be disconnected to run the pretest because it issues an STF instruction to all SC's. The same applies for all I/O related diagnostics which employ a basic I/O test.

If the 12979B Dual-Port I/O Extender is installed and pretest or any I/O related diagnostic is to be run, the extender should be "locked" to the port (either A or B) that the computer running the diagnostic is connected to.

Full system dedications is required during loading and configuring the Configurator. This also applies to all associated components of the diagnostic input device.

2-1. OPERATIONAL OVERVIEW

This section describes the procedures for loading the Configurator, executing the Pretest, configuring the Configurator, and loading the diagnostics. The operating procedures are shown in flowcharts with notes where necessary for clarification.

There are three procedures for configuring the program: Conversational, Automatic, and Manual. The Conversational method provides a means of configuring the program from the console with one input from the S-Register and utilizing the parameters calculated by the program. This method is recommended for the user who is not familiar with the Configurator. The Automatic method provides a means of configuring the program with one input from the S-Register (A- and B-Registers) and utilizing the parameters calculated by the program. The Manual method provides a means of configuring the program using the S-Register exclusively and allows modification of the parameters calculated by the program.

The Conversational or Manual methods of configuration must be used when a line printer is required by a diagnostic.

Prior to configuration, the operator may execute the Pretest to ensure that the basic instructions of the CPU can be executed and the drivers will be configured correctly.

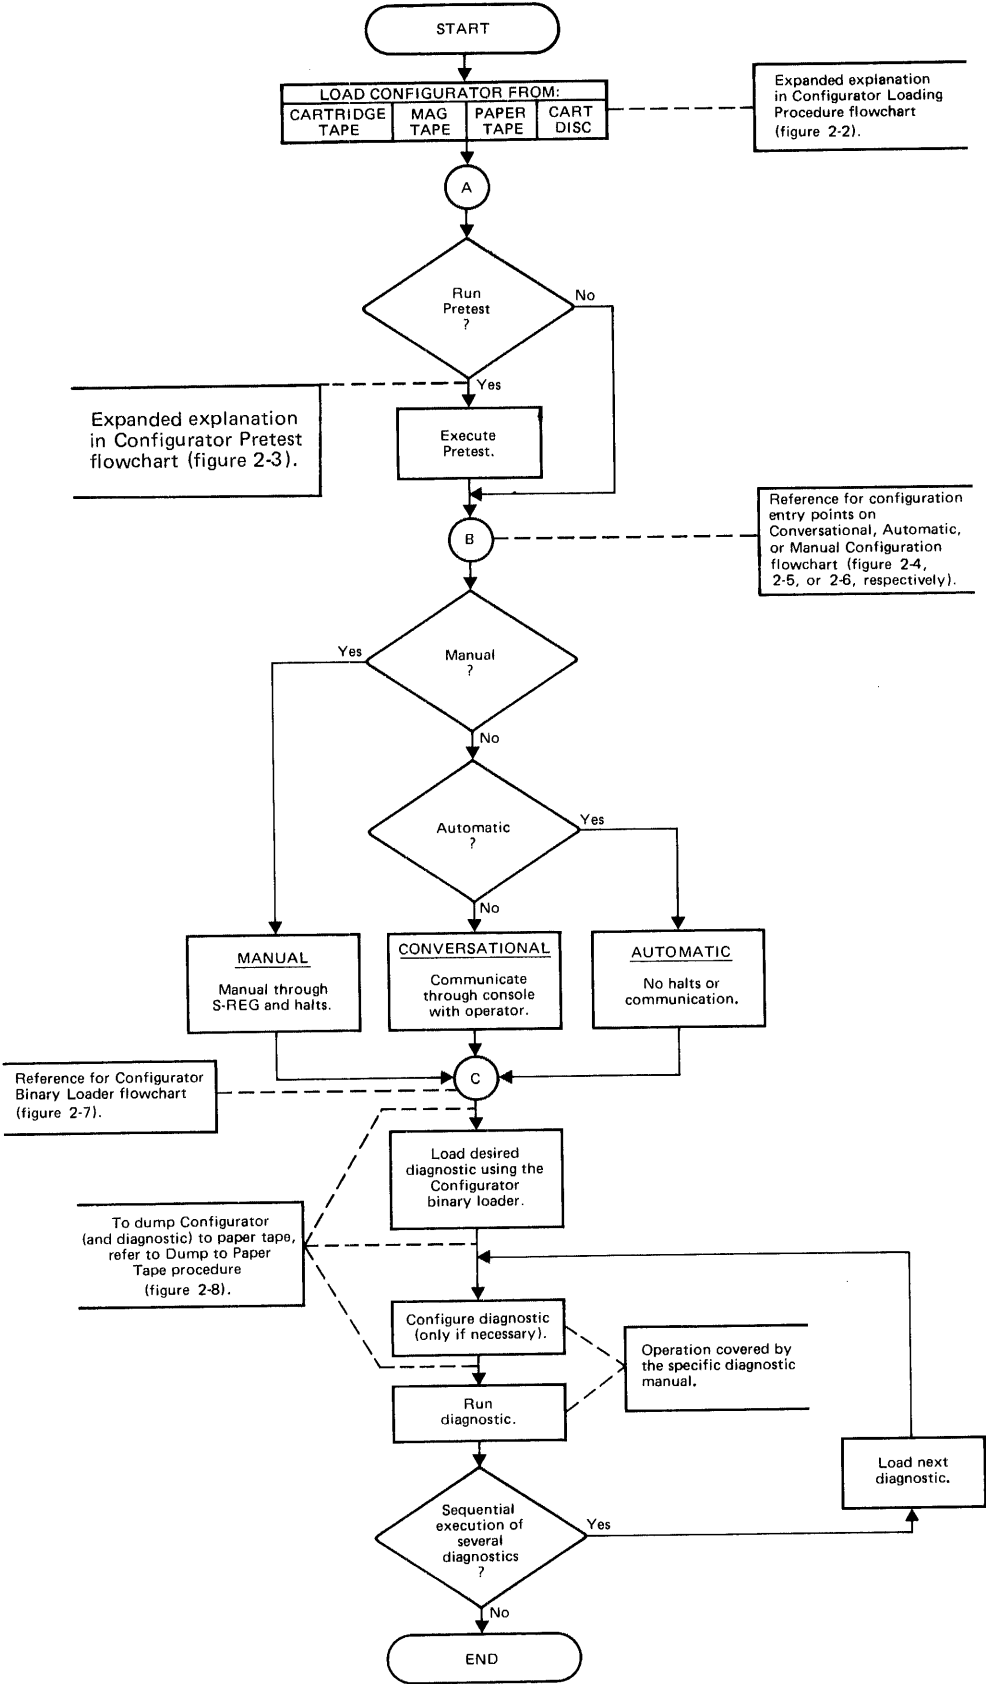

A general loading procedure flowchart for the various devices and computers is furnished as a quick reference in figure 2-1.

The basic configuration procedure is:

1. LOAD THE CONFIGURATOR PROGRAM (figure 2-2).

Note: Immediately after loading the Configurator (a diagnostic or a control program), the Diagnostic Serial Number (DSN) which resides in memory location 126 (octal) may be checked for a match with the information shown in the left-hand column of table A-1 in appendix A of this manual.

2. SET P-REG TO:
 - (a) 2 → to execute the Pretest prior to configuration (figure 2-3).
 - (b) 100 → to start configuration directly.

7132-1

Figure 2-1. Operational Overview Flowchart

2-2

3. SET S-REG TO: (a) The console select code (Conversational, figure 2-4).

-or-

- (b) The console select code, diagnostic input device select code, and diagnostic input device type. Set bit 15 if the A-Register specifies a DSN and the B-Register the diagnostic to be loaded and executed following the specified DSN (Automatic, figure 2-5).

-or-

- (c) Clear (Manual, figure 2-6).

4. PRESS PRESET, RUN.

Note: Running time for the Configurator is entirely dependent upon the selection or deletion of the Pretest, the mode selected, and operator response time. (The Pretest requires approximately 10 seconds for a CPU with 32K of base memory.)

2-2. CONFIGURATOR LOADING PROCEDURE

Figure 2-2 is the flowchart for loading the Configurator. Paragraph 2-10 provides information for loading diagnostics after the Configurator is loaded and configured.

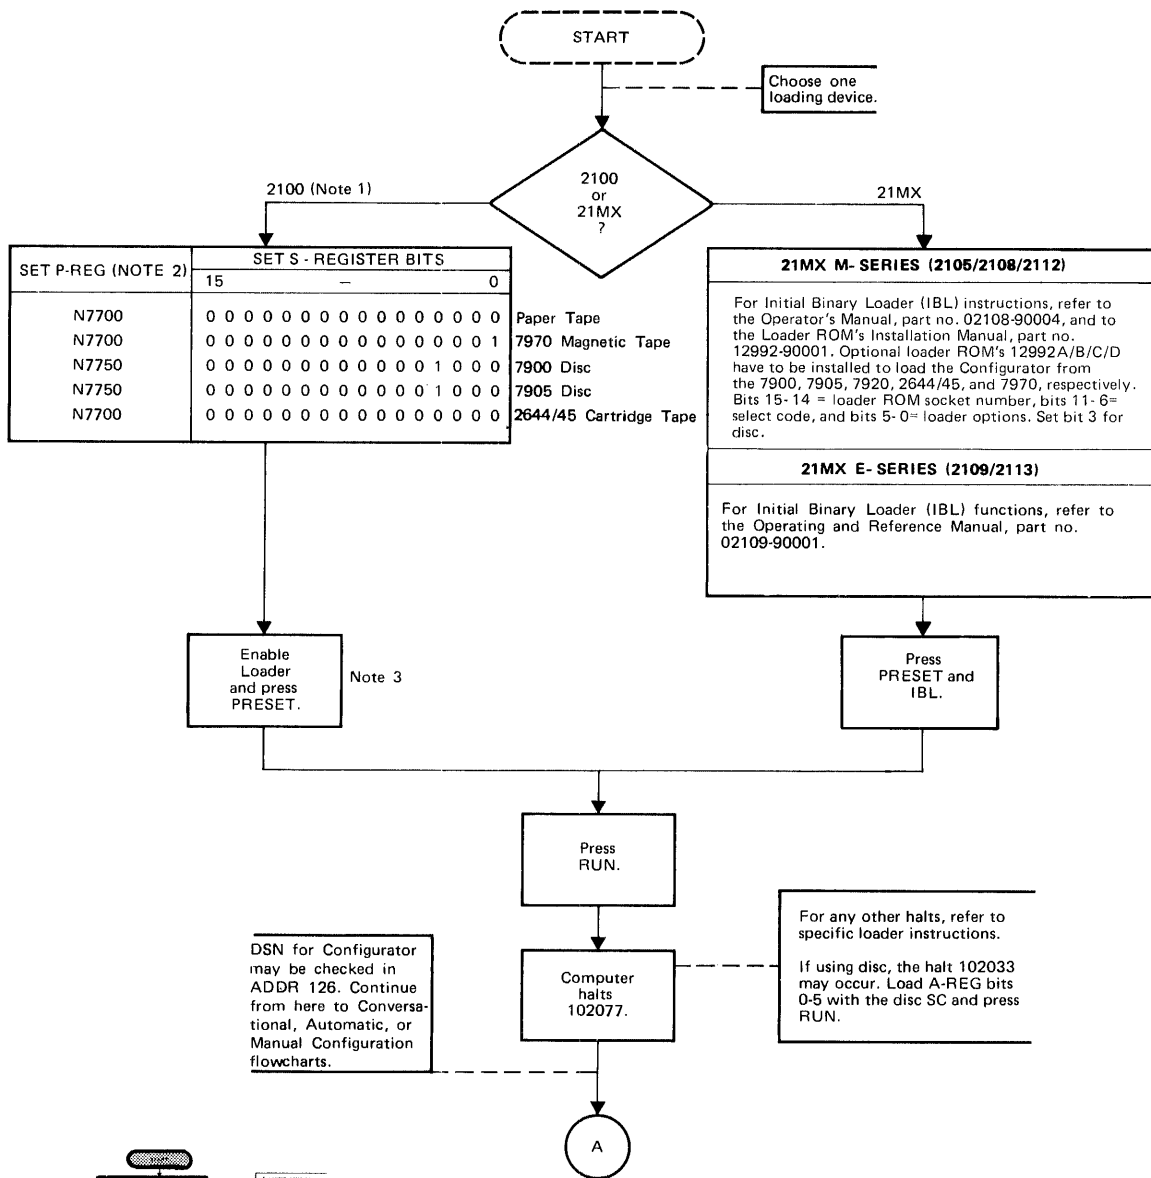

2-3. REGISTER USAGE

The following describes the use of the four registers (P, S, A and B) during configuration and the loading of diagnostics. The P-Register, as shown in the table below, shows the starting address of the various programs and the required registers.

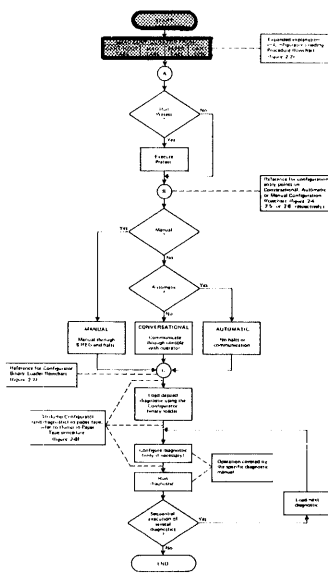

P-REGISTER	PROGRAM SELECTION	REQUIRED REGISTERS
2	Execute Pretest	S-A-B
100	Configure Diagnostic Configurator	S-A-B
120	Load Diagnostics	A-B
N7677	Dump to Paper Tape	S

2-4. S-REGISTER

As shown in the table below, the S-Register is used to indicate which configuration mode (Automatic, Conversational, or Manual) shall be used. If only the console is specified, then Conversational is used. If the console and the input device are specified, then Automatic is used. If the S-Register is left clear, then Manual is used. If a legal but incorrect SC is given for an I/O device, the result is unpredictable.

- NOTES: 1. HP 2100 or earlier (2114A/B, 2115A, 2116A/B/C).
 2. N = 0 for 4K, 1 for 8K, 2 for 12K, 3 for 16K, 4 for 20K, 5 for 24K, 6 for 28K, and 7 for 32K.
 3. For 2114A/B, press PRESET and LOAD simultaneously.

7132-2

Figure 2-2. Configurator Loading Procedure Flowchart

During the Paper Tape Dump routine, the SC of the punch is specified in the S-Register. (Refer to Dump routine in paragraph 2-11.)

S-REGISTER	INTERFACE TYPES & SELECT CODES	
	CONFIGURE (PRETEST)	DUMP ROUTINE
5-0	Console Select Code	Punch Select Code
11-6	Input Device Select Code	
14-12	Input Device Type	
15	Additional Parameters (in A- and B-Registers)	

2-5. A- AND B-REGISTERS

The two working registers have a special meaning when employed in conjunction with the Configurator Binary Loader. (See table 2-1.)

The A-Register has to be either loaded with the DSN of the diagnostic to be read into memory (and executed) or be cleared, in which case the next sequentially stored file in the input device will be loaded (and executed).

The B-Register has to be loaded with the bit pattern representing the appropriate diagnostic files to be loaded (and executed) following the diagnostic specified by the A-Register. B-Register bit 0 set will call for the execution of the diagnostic specified by the A-Register, bit 1 set will call for the execution of the next sequential diagnostic (file), etc. If the B-Register is cleared, the diagnostic specified in the A-Register will be loaded but not automatically executed. If any bit or bits are set in the B-Register, it will load and start execution of the selected diagnostic.

If both the A- and B-Register are not clear the Configurator will, after the specified diagnostics have been executed, return (rewind) to the first diagnostic specified and repeat the execution; i.e., loop on selected diagnostics.

Table 2-1. Summary of A- and B-Register Concept

B-REGISTER	A-REGISTER	
	CLEARED	SET TO DSN
Cleared	Load next file (diagnostic) and halt before execution.	Load specified diagnostic and halt before execution.
Set to bit pattern	Load next file and execute from there on each diagnostic specified in the B-Register one time.	Load specified diagnostic, execute from there on each specified diagnostic, and loop on all selected diagnostics.

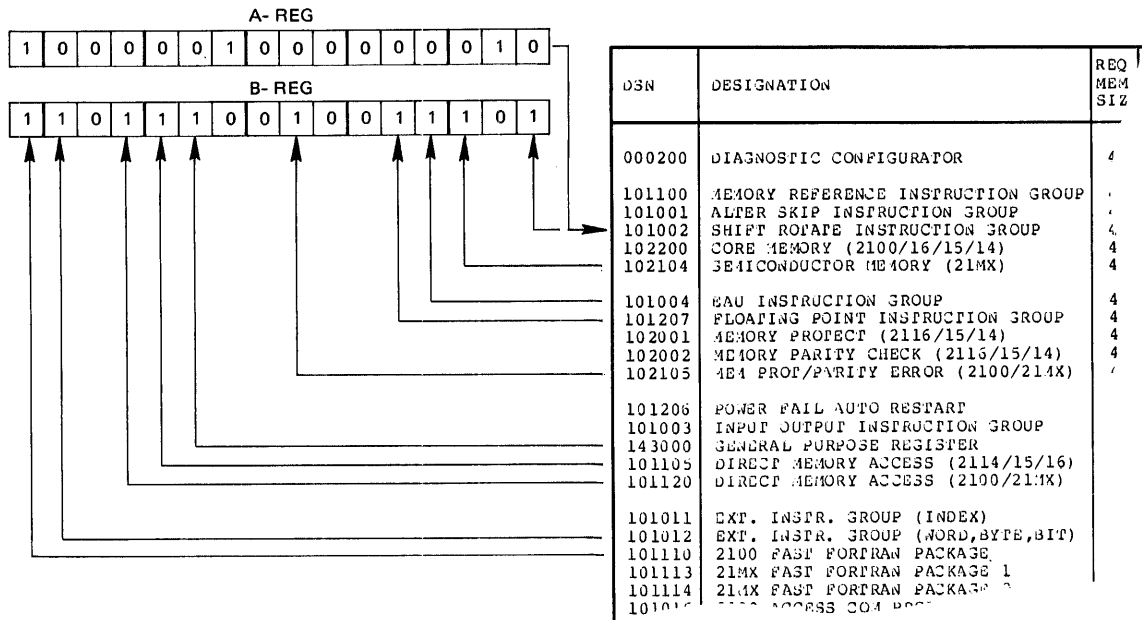

This concept enables the user to concatenate his own Long Diagnostic with the desired diagnostics. The A- and B-Registers are set prior to Automatic configuration (see paragraph

2-8) and at the end of Manual configuration (halt 102077; see paragraph 2-9). In the Conversational mode, the user inputs the information via the terminal in response to the message: DSN (,SEQ.DIAG.EXECUT.) . . .

Example: A-REG → 101002: B-REG → 156235

A-REG → 101002: Load Shift-Rotate Instruction Group Diagnostic.

B-REG → 156235: Execute Shift-Rotate Instruction Group diagnostic, then load and execute sequentially the specified diagnostics.

If in the above example the B-Register carries the value 156234, the Shift-Rotate Instruction Group diagnostic will not be executed.

After the 2100 Fast FORTRAN Package diagnostic has been executed and the diagnostic media is disc or magnetic tape, the diagnostic execution will restart. In case of cartridge tape or paper tape, an end-of-tape halt 106070 will be reached at an earlier point. This is because the cartridge tape number 1, with 17 files stored, reaches an EOF after the DMA/DCPC (2100/21MX) diagnostic. In case of paper tape, the first EOF will be reached after the semiconductor memory diagnostic.

2-6. CONFIGURATOR PRETEST

This procedure provides a means to execute the Pretest (which is loaded as part of the Configurator) prior to any configuration. It should be used whenever the CPU, memory, or

basic I/O is in question. When it is executed and an error halt 102066 is encountered, the operator should refer to the listing in appendix D. An error-reporting method via a console is not employed for the Pretest because it verifies the basic integrity of the CPU, base memory, and basic I/O, which is a prerequisite for transferring data to a console. The approximate run time for the Pretest is 10 seconds for 32K of memory.

The memory section of the Pretest checks only the base memory. The basic I/O section of the Pretest requires a standard* I/O interface board with its SC specified. If installed, disconnect WCS accessory. The Configurator Pretest flowchart is shown in figure 2-3.

2-7. CONVERSATIONAL CONFIGURATION

This procedure, which provides a fully conversational configuration from the console, must be used when a line printer is required**. It should also be used (if possible) when the operator is not familiar with the program operation. This procedure requires a console with one of the console interfaces listed in paragraph 1-2c. The Conversational Configuration flowchart is shown in figure 2-4.

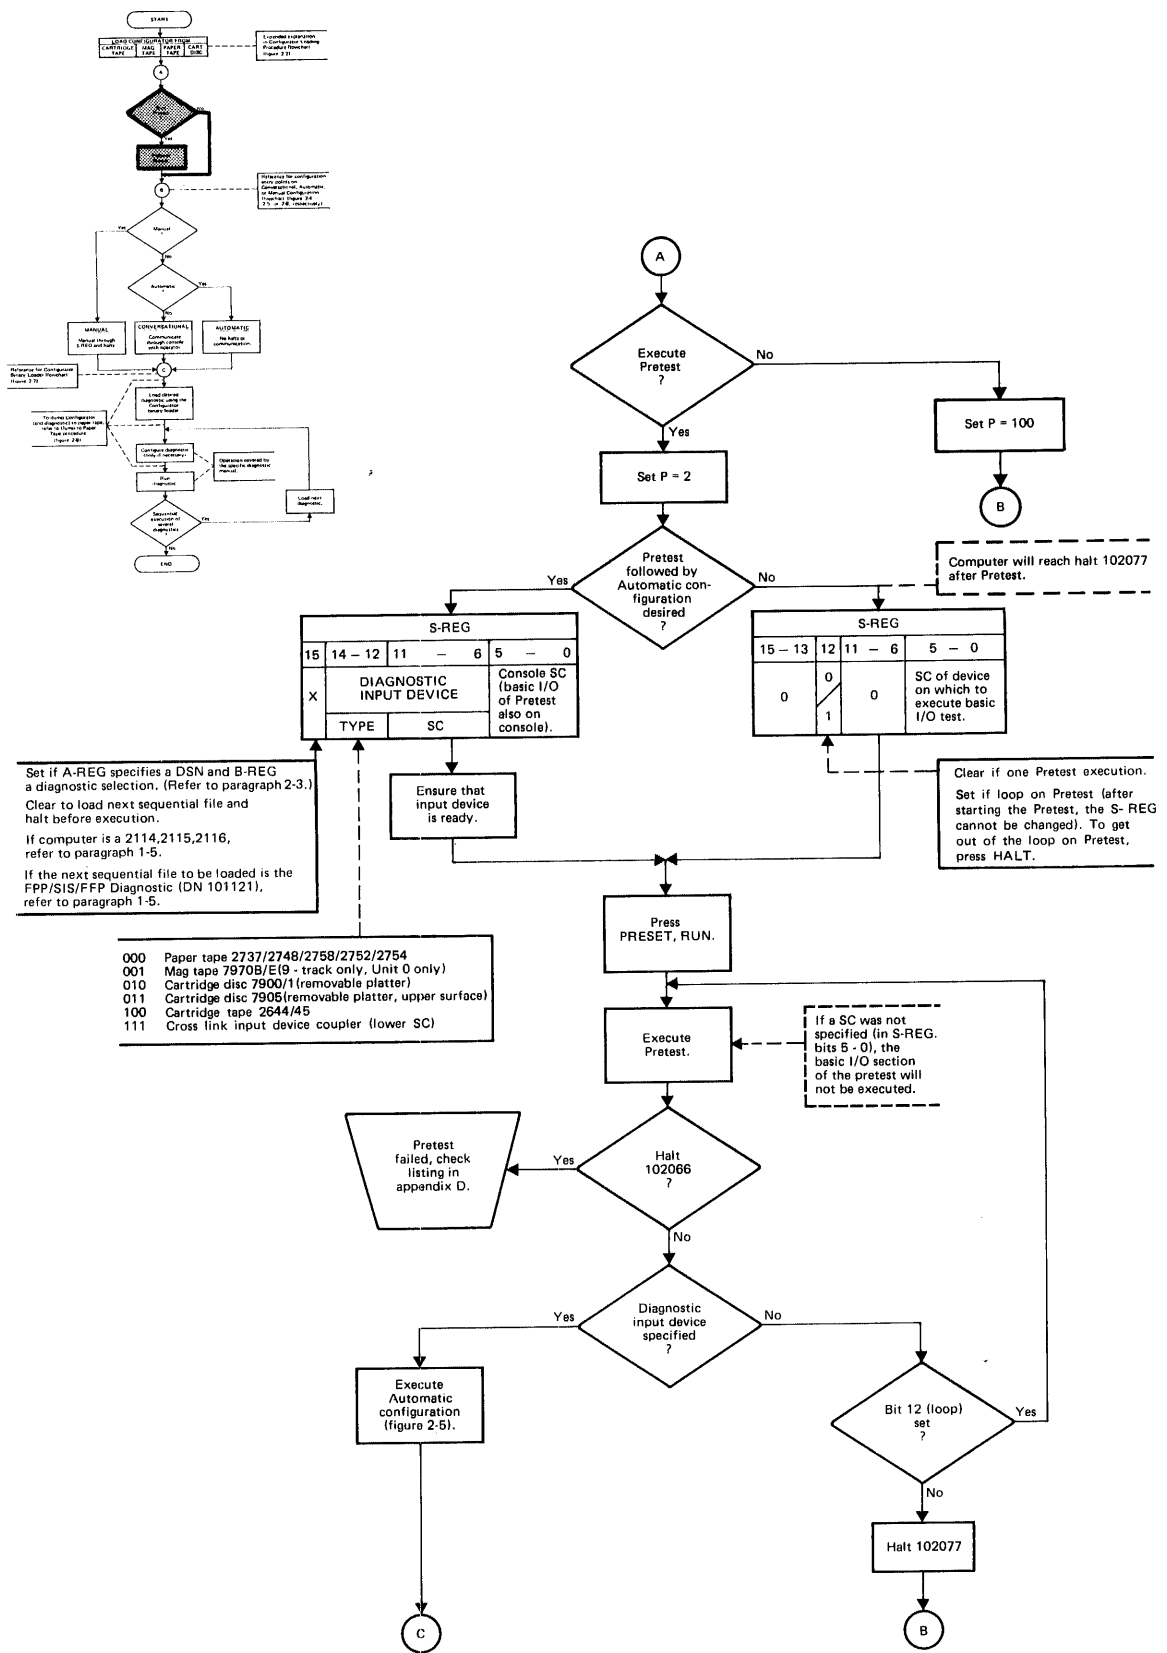

All inputs are terminated by a CR (carriage return). If an entry is found incorrect prior to entering a CR, the input can be erased by entering a RUBOUT/DELETE. In reply, the program will issue a CR/LF (line feed).

2-8. AUTOMATIC CONFIGURATION

This procedure provides a means to configure the program and load a diagnostic with one input from the S-Register. There are no messages on the console. The program configures the appropriate drivers and then loads a diagnostic. Because there is no report of what is calculated by the program, the operator must assume that the calculations were made correctly. For Automatic Configuration, figure 2-5 shows the expansion of point B to point C from the Operational Overview flowchart.

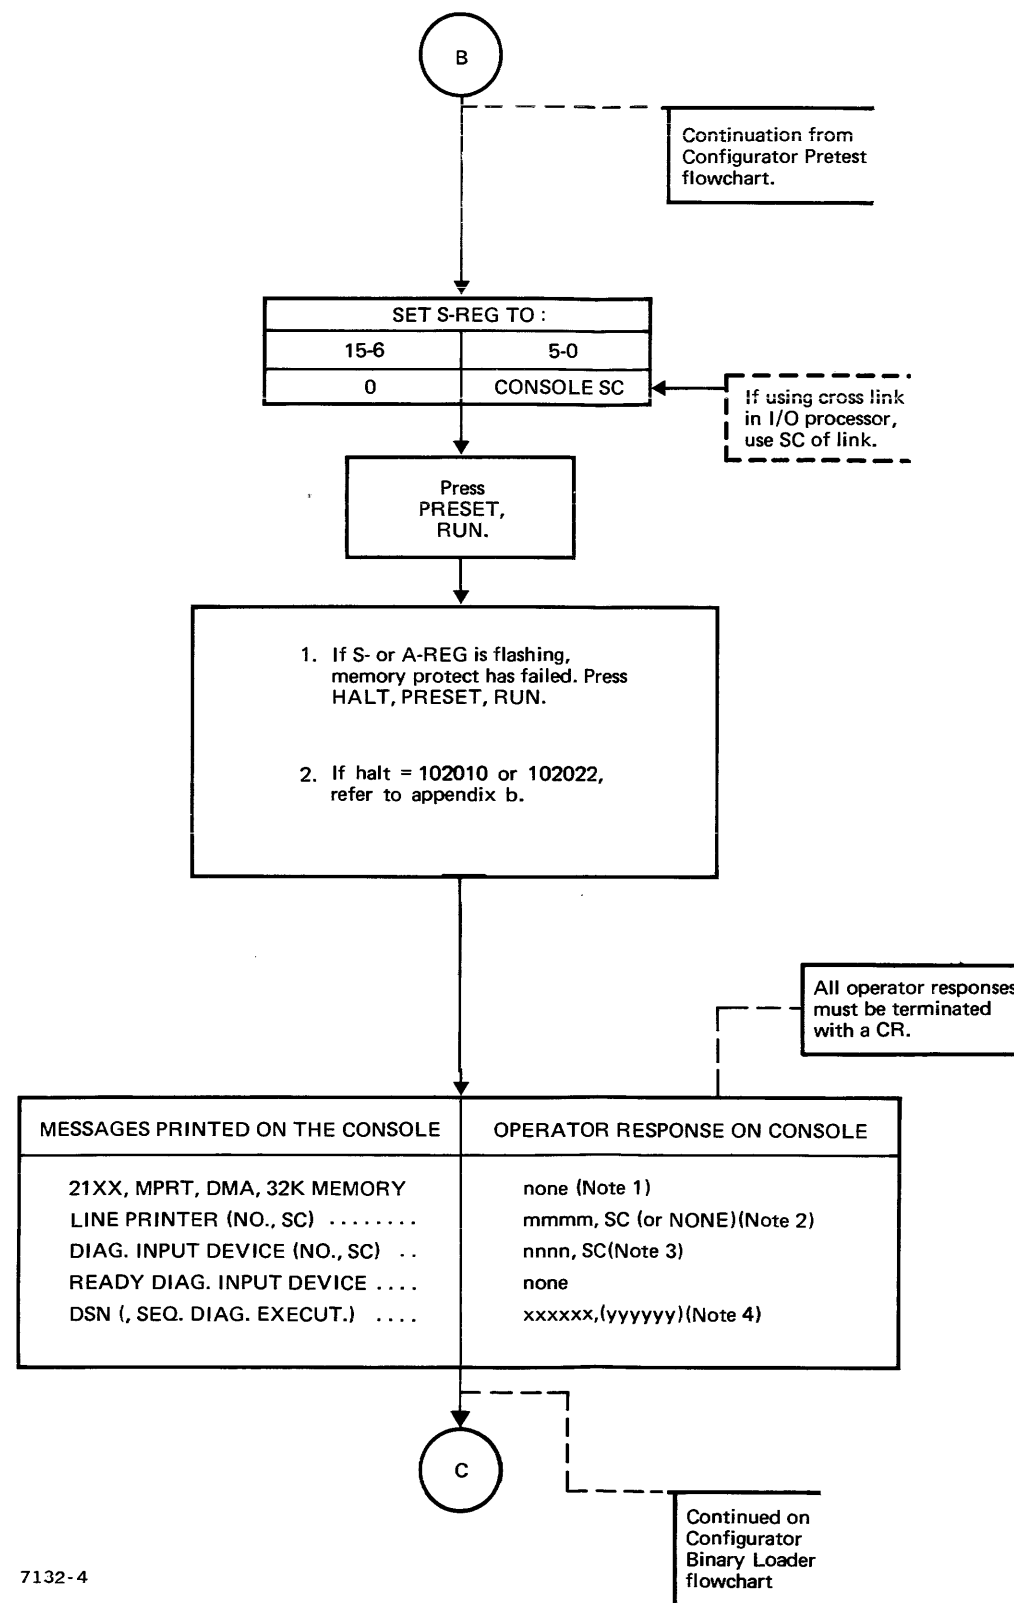

*Standard I/O implies that the interface will respond to the assigned meaning of the I/O instructions and will also interrupt when control and flag are set and the interrupt system is enabled, (e.g., the 12665-60001, 59310-60101, 13175A, and 13178B interfaces cannot be used).

**Manual method may also be used to specify (configure) a line printer driver.

7132-3

Figure 2-3. Configurator Pretest Flowchart

Console Configuration Notes:

- No response to this message is required. The printout shows the parameters calculated by the program. They are listed for operator reference only. The actual printout will depend on the computer and its options:

21MX M, 21MX E, 2114, 2115, 2116, 2100	Computer type (21MX E refers to the E-Series and F-Series computer)
NO MPRT or MPRT	Memory protect
NO DMA or DMA	Direct Memory Access/Dual Channel Port Controller
32K MEMORY	Calculated base memory size, this does not include Memory Expansion Unit.
- Respond with the appropriate line printer model number and select code.

mmmm	= 2767, 2610, 2614, 2613, 2617, 2618, 2778, 2607 or 9866
	NONE (if not available)
	LINK (if cross link is used)
SC	= Line printer select code.
- Respond with the appropriate device number (or LINK) and select code.

nnnn	= 2737, 2748 or 2758	Paper tape devices
	= 7970	Mag tape (9 - track only, Unit 0 only)
	= 7900 or 7901	Cartridge disc (removable platter only)
	= 7905/20	Cartridge disc (removable platter, upper surface)
	= 2644 or 2645	Cartridge tape (input 2645 if using 2648)
	= LINK	(if cross link input device coupler is used)
SC	= select code of device	(Lower SC in case of 2 SC)
- Respond with the desired Diagnostic Serial Number for the indicated value of xxxxxx. Refer to appendix A for a list of available diagnostics and their DSN's. If 0 is entered, the next consecutive binary file will be loaded from the input device.

The value yyyyyy may be entered for the octal equivalent of the binary bits selecting the desired diagnostic. (The program will load the values xxxxxx into the A-REG and yyyyyy into the B-REG and interpret as explained in paragraph 2-3.) If yyyyyy is not entered, the program sets the B-REG to 000000.

Figure 2-4. Conversational Configuration Flowchart

Figure 2-5. Automatic Configuration Flowchart

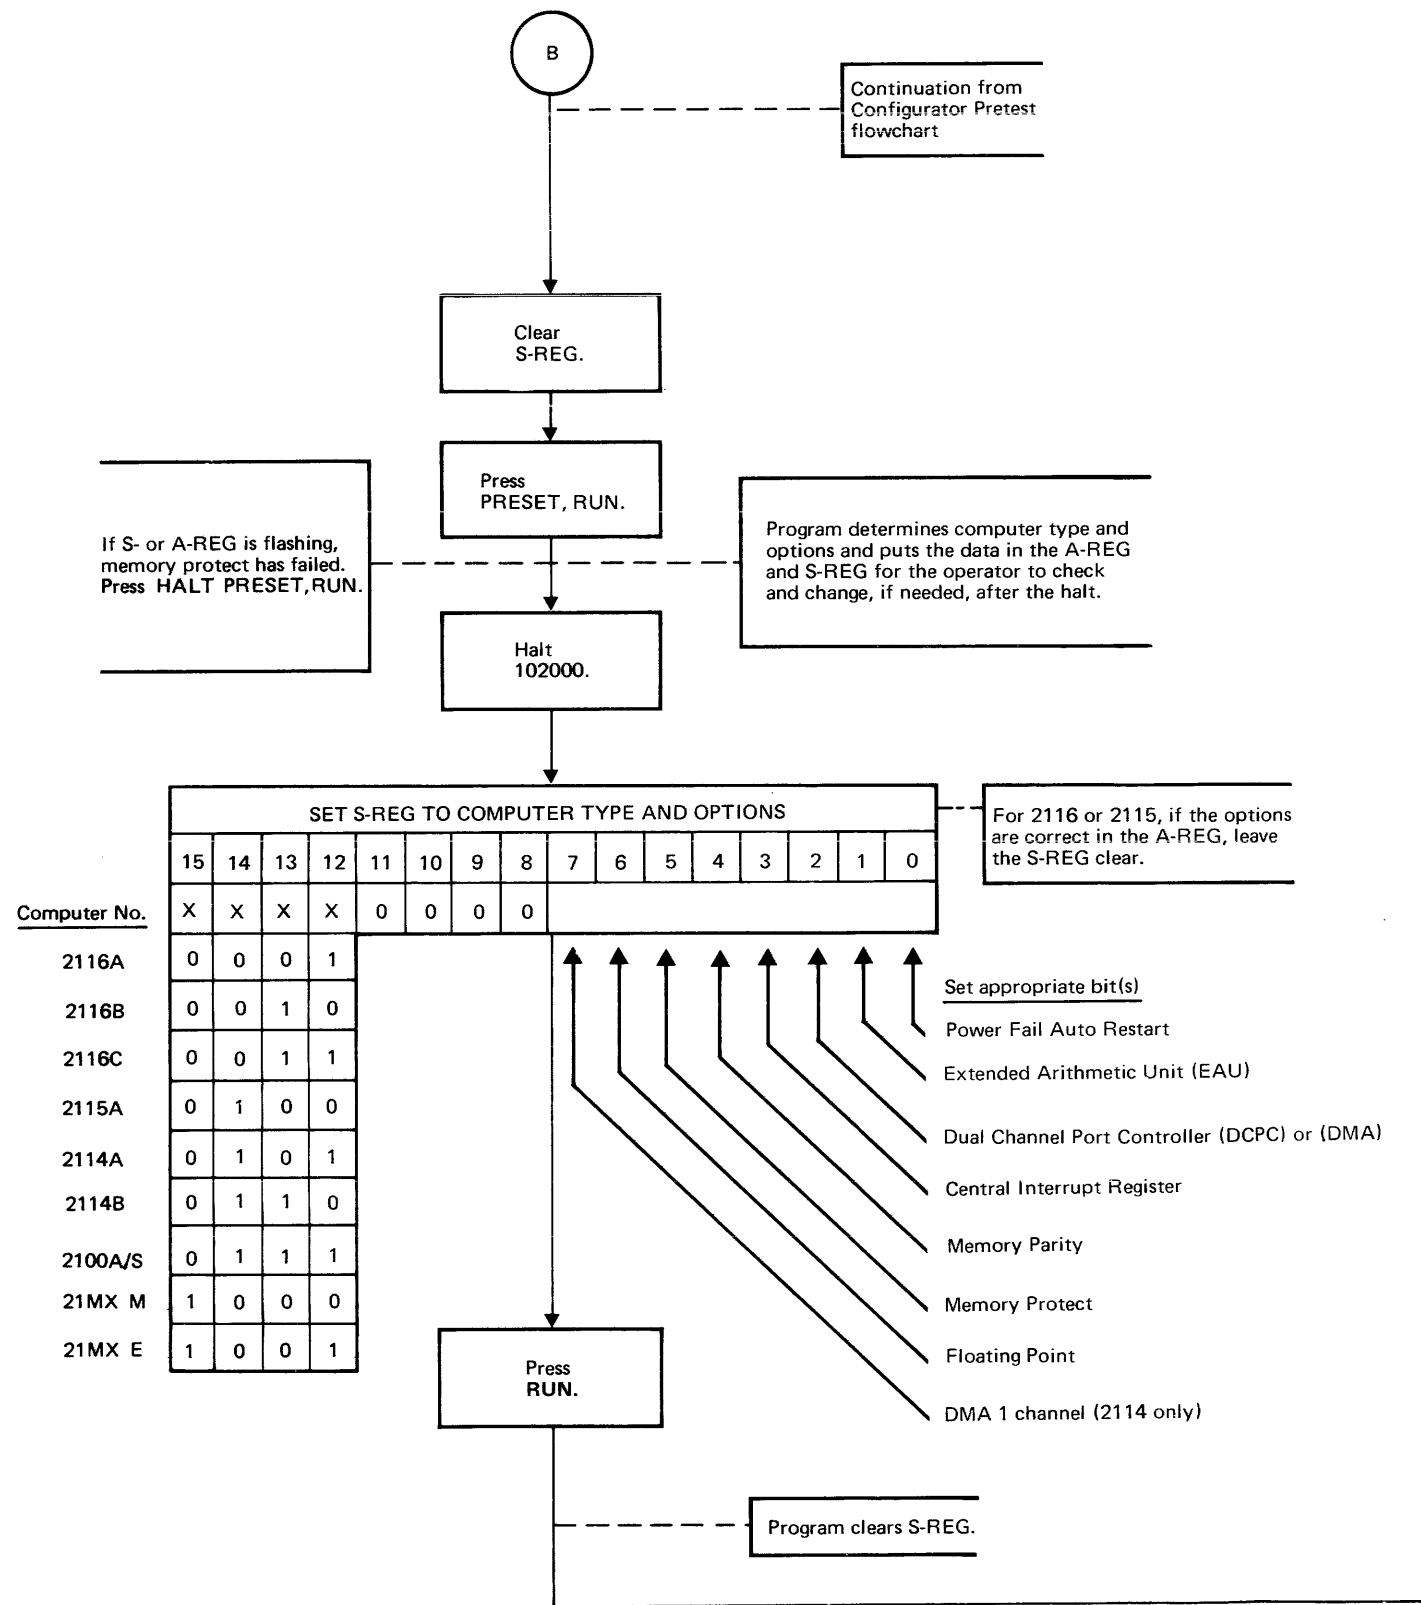

2-9. MANUAL CONFIGURATION

This procedure allows complete configuration through the S-Register via five halts. The program calculated parameters are displayed in the A- and S-Registers at the appropriate halts (0 and 3). When the operator presses RUN, the S-Register is read and the information supersedes the calculated value.* The basic halts and required inputs are:

HALTS	INPUT
102000	Computer type and options.
102001	Console interface type and select code.
102002	Line printer type and select code.
102003	Memory size.
102004	Diagnostic input device type and select code.
102077	Configuration complete.

After halt 102077, the program exits to the Configurator Binary Loader routine to accept a DSN in the A-Register and a sequential execution bit pattern in the B-Register. (Refer to paragraph 2-3b.) The Manual Configuration flowchart is shown in figure 2-6.

*If the S-Register is cleared at halt 102000, the program calculated parameters are used for configuration. This is ordinarily useful on the 2116 and 2115 where the S-Register is already cleared and the A-Register contains the correct parameters.

Baud Rate for 12966/12968 only

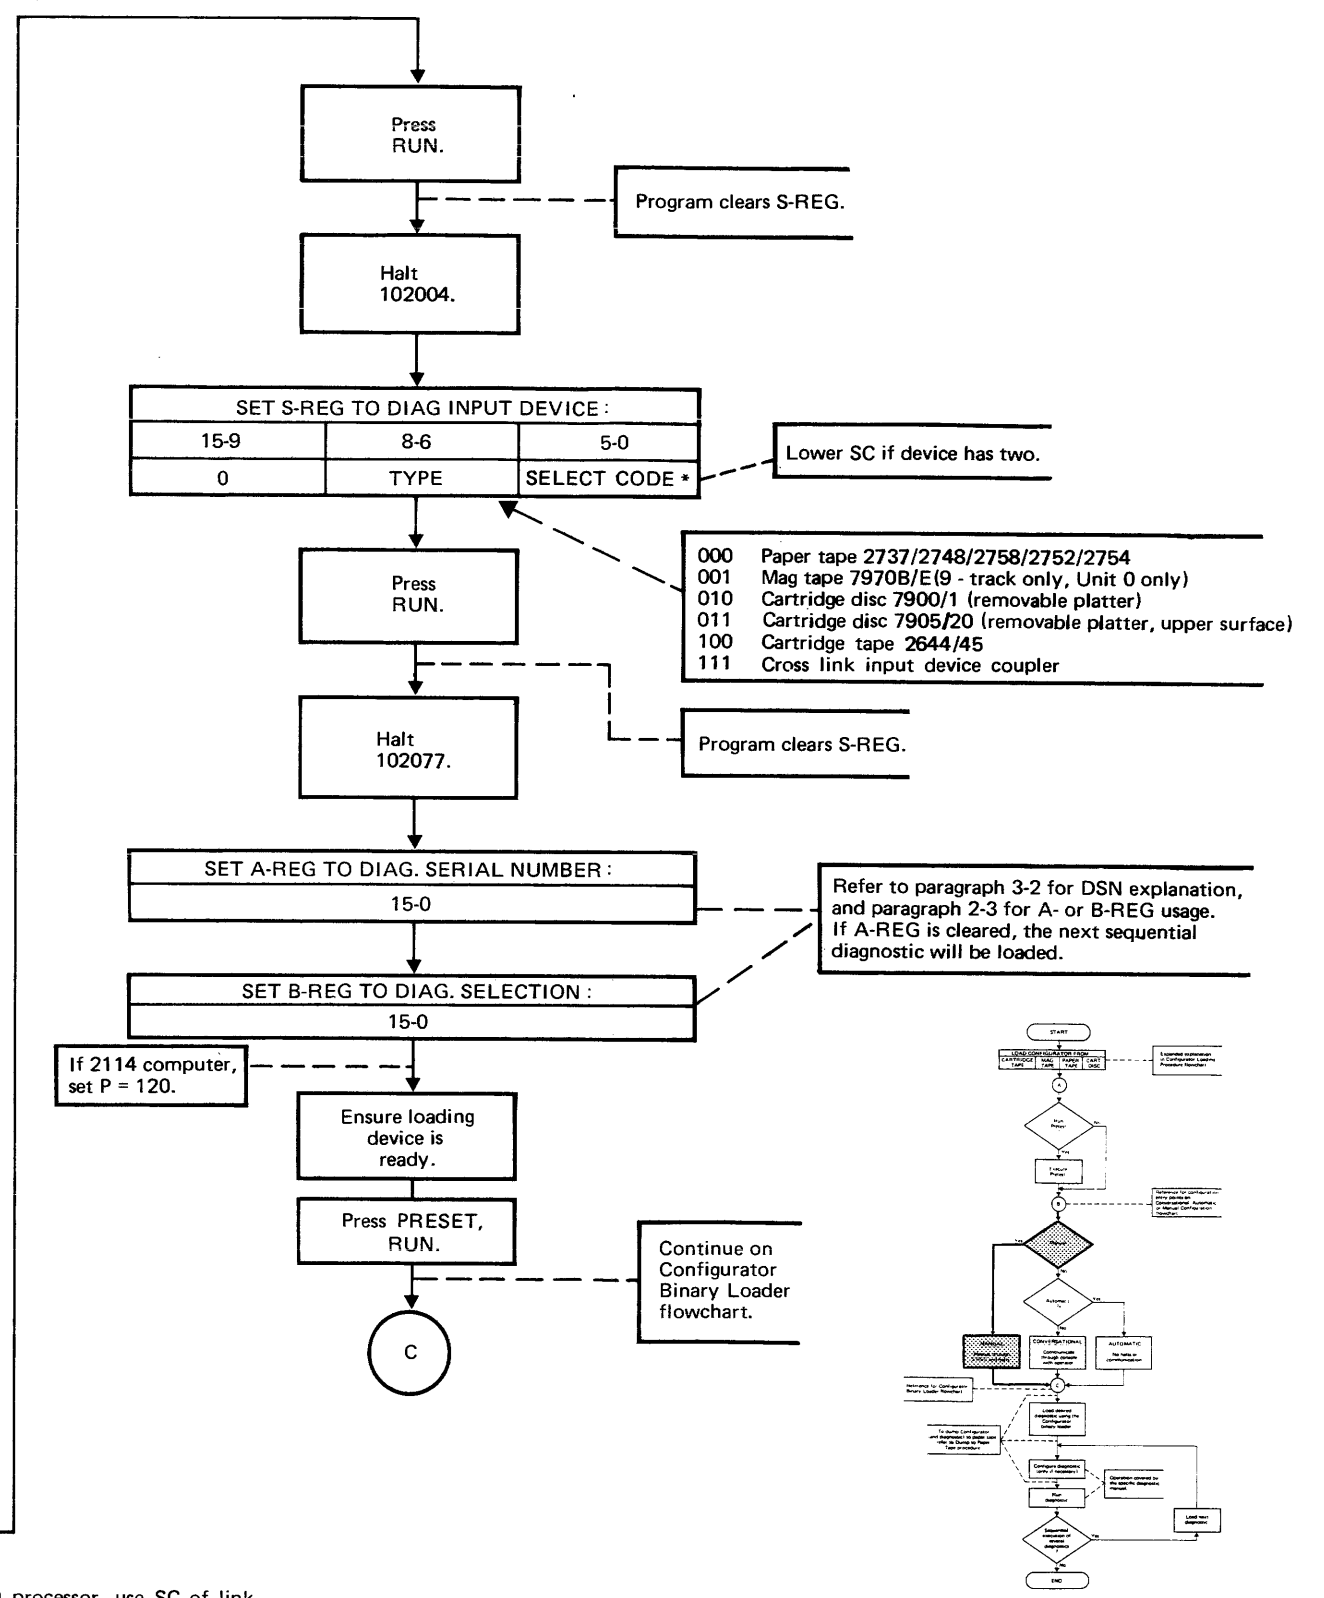

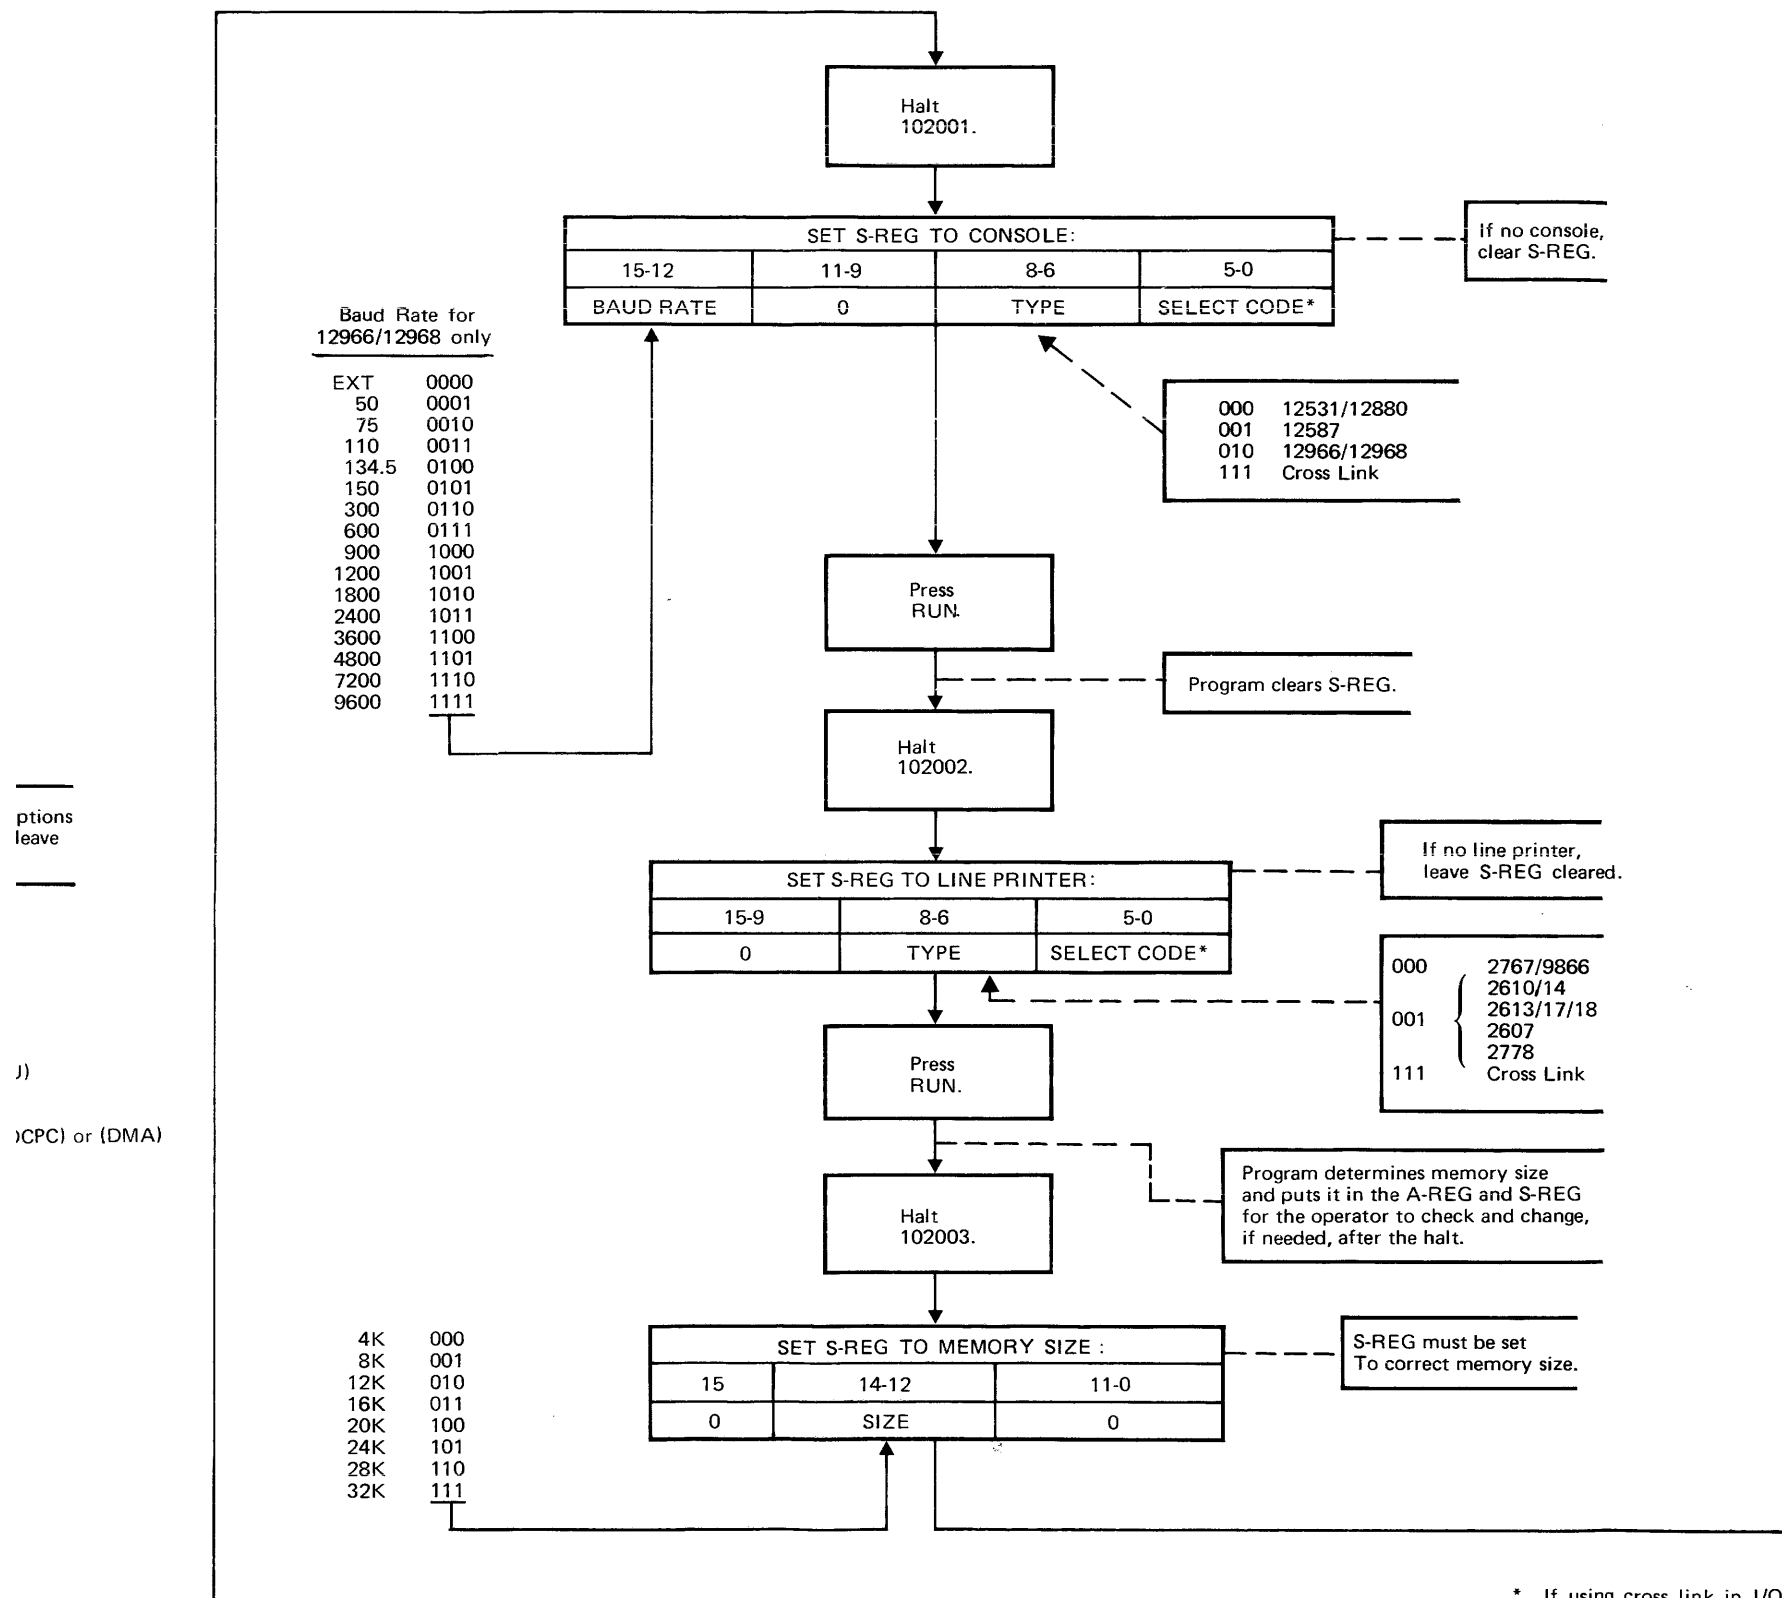

EXT	BAUD RATE

* If using cross link in I/O processor, use SC of link.

Figure 2-6. Manual Configuration Flowchart.

2-10. CONFIGURATOR BINARY LOADER

The Configurator Binary Loader is used to load diagnostic programs from the following devices:

- a. Paper Tape Readers; (Type 0)*: HP 2737, 2748, 2758, or teleprinter with paper tape reader.
- b. Magnetic Tape; (Type 1)* (requires DMA/DCPC), (Unit 0 only): HP 7970B/E 9-track only, interfaces = 13181, 13183, 18184.
- c. Cartridge Disc; (Types 2 and 3)* (requires DMA/DCPC), (Unit 0 only): HP 7900/1 Removable platter or HP 7905 Removable platter, upper surface.

The loader utilizes memory addresses N6300 through N6500 as a sector buffer for the disc loader. Diagnostics are loaded starting at address 130 and they may extend into the sector buffer area. Therefore, prior to loading the diagnostic, the upper memory boundary required to load the diagnostic is tested. If it reaches beyond N6300, the loader program will halt with 106073 displayed. Three possible routes can then be chosen by the operator as follows:

- (1) Load the desired diagnostic from a different device.
 - (2) Restart the loader and specify another DSN.
 - (3) Continue loading the diagnostic from disc but be aware that the overlaid buffer may cause unpredictable results.
- d. Cartridge Tape; (Type 4)*: HP 2644 or 2645 Terminal with 12966 interface.
 - e. Cross Loader Coupler; (Type 7)*: This is not a true loader but it allows the program to cross link to a loader driver in the central processor. The data checking (checksum and address violation) is done in the I/O processor (or slave) and only the device driver is used in the central processor. (See paragraphs C-10 through C-14.)

When using the loader, the files are searched until the specified Diagnostic Serial Number is found. If the specified DSN is not found, the program will halt 106070. When the Configurator Binary Loader has loaded the desired diagnostic and the B-Register was cleared, the program halts 102077 with the A-Register carrying the DSN contained in address 126.

To load the next consecutive binary file, clear the A- and B-Registers, set P=120, press PRESET and RUN.

All files are assumed to be absolute and the record length is not longer than 60 words including the count, address, and checksum. The flowchart for the Configurator Binary Loader is in figure 2-7.

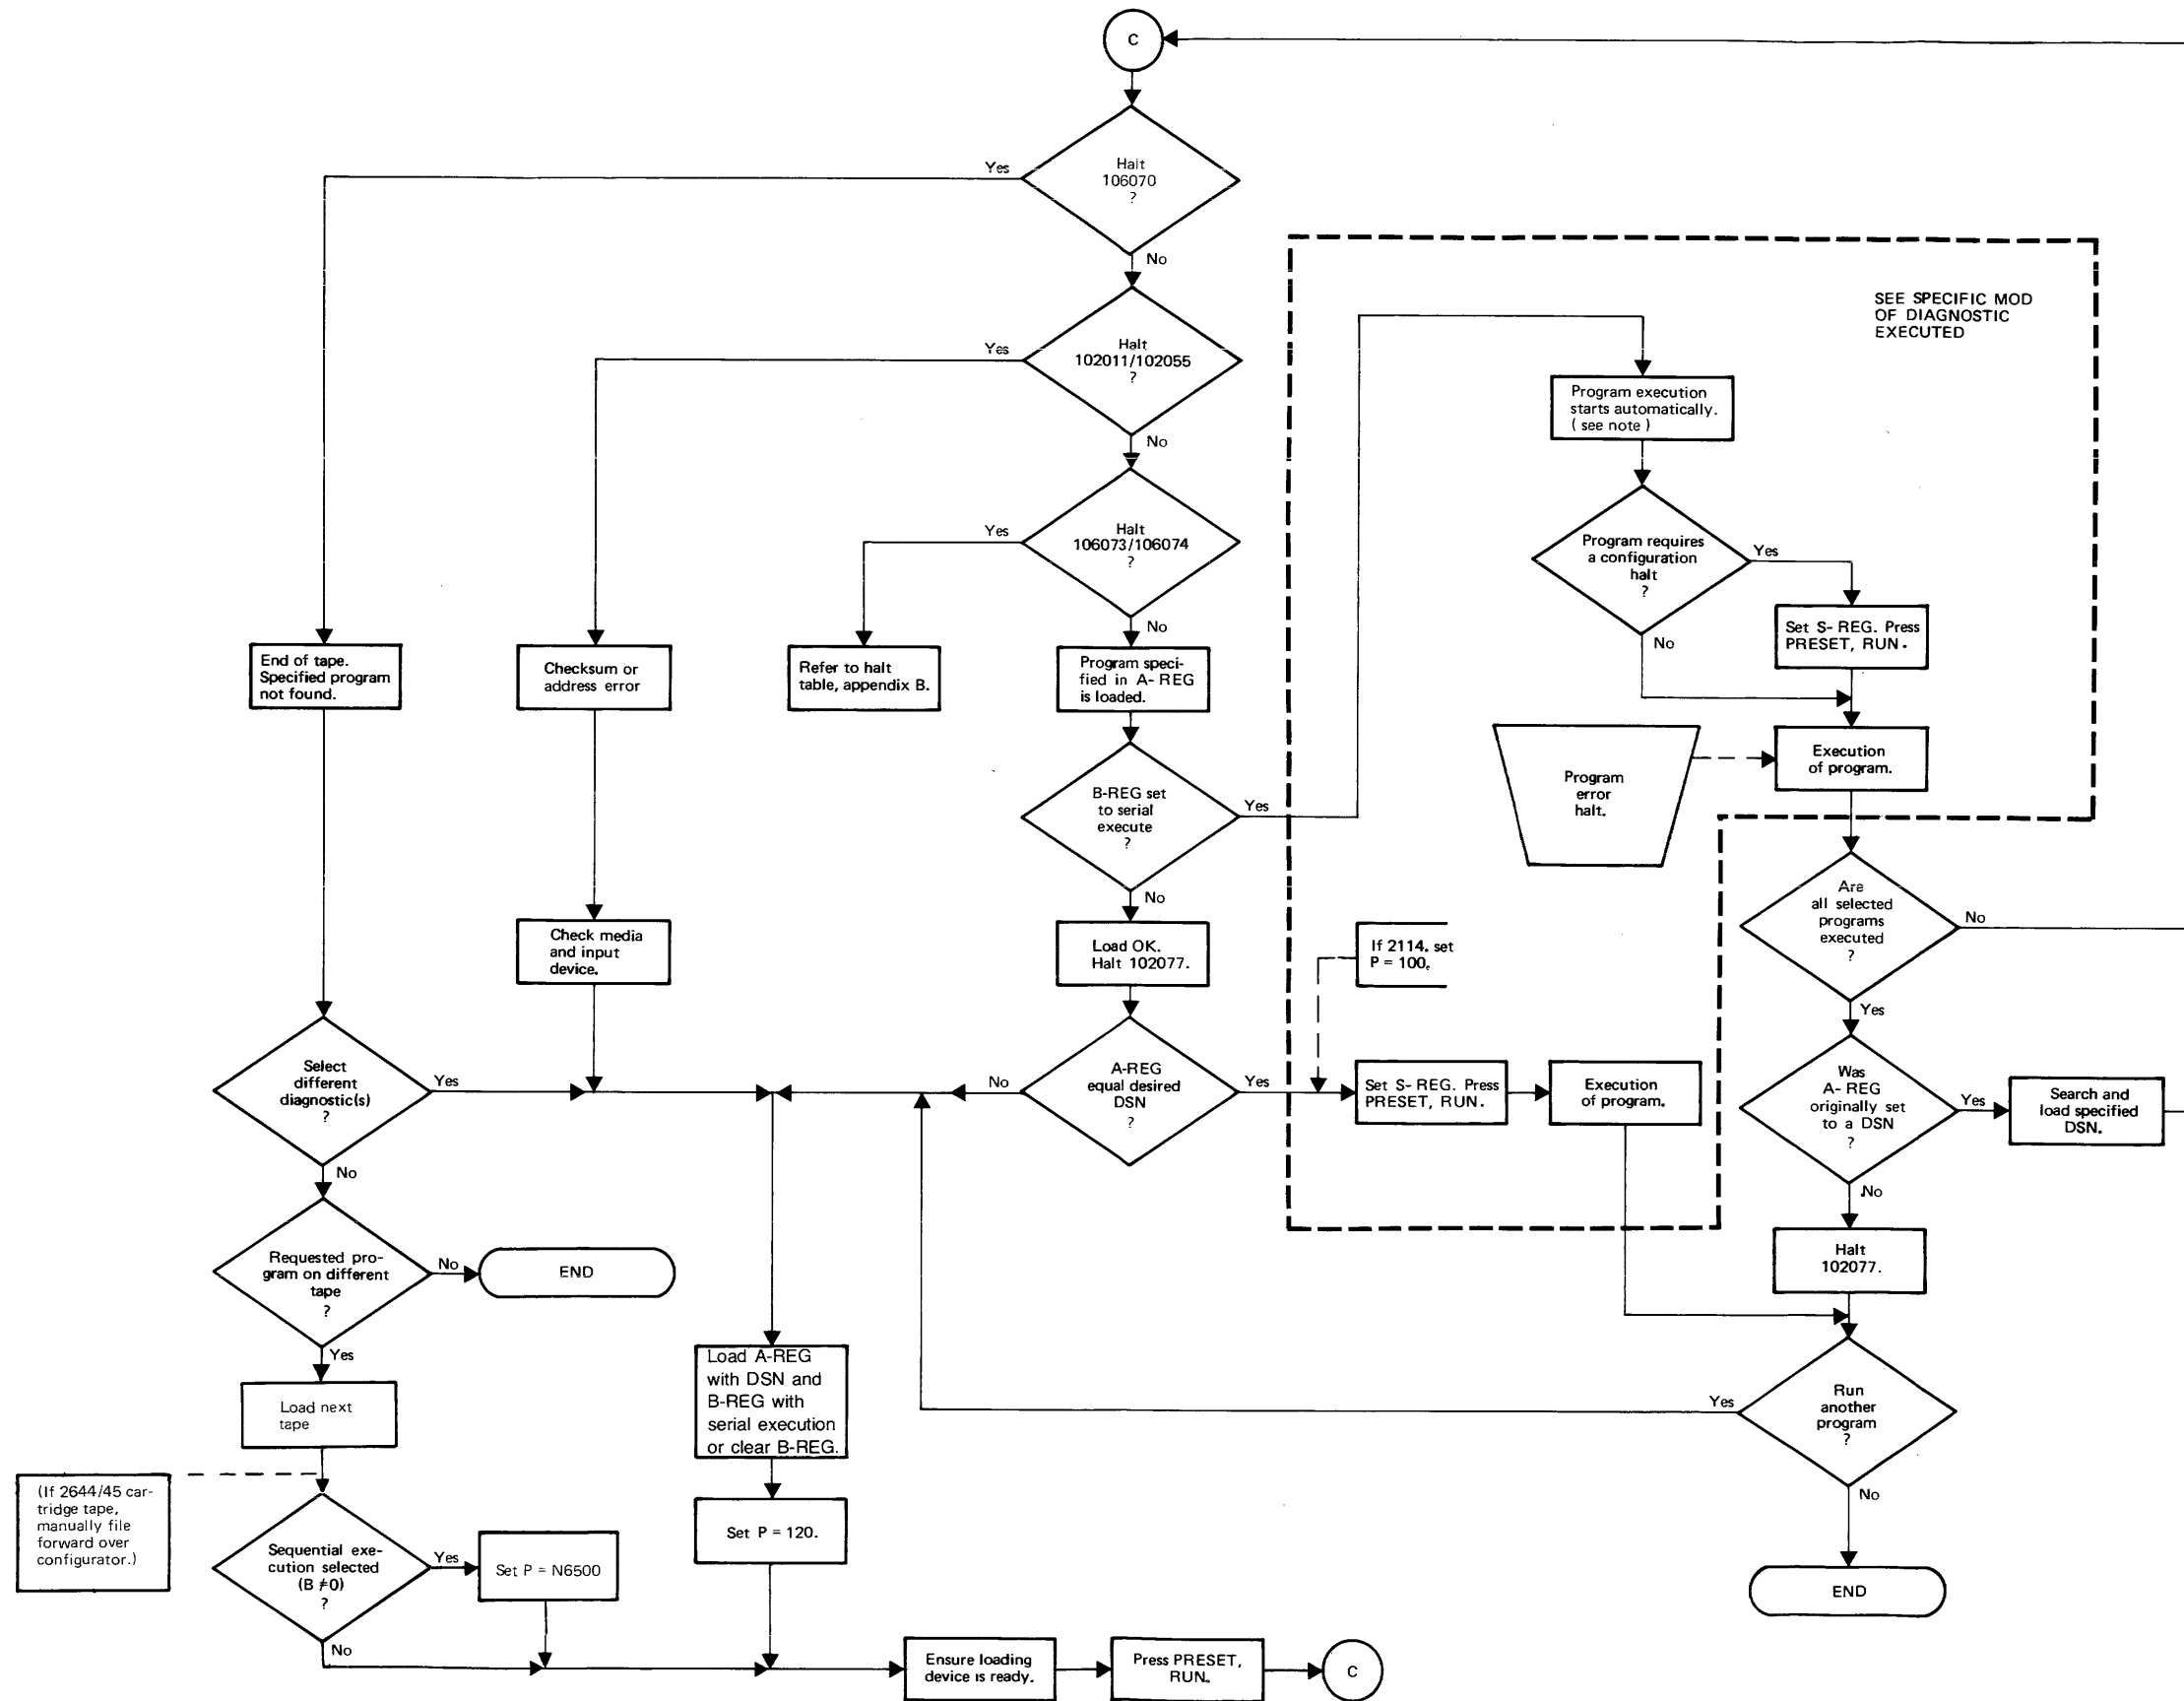

*Type numbers refer to S-Register bits 14 through 12 in Automatic Configuration and S-Register bits 8 through 6 after halt 102004 is reached in Manual Configuration. They are also placed in memory location 111 with the select code.

2-11. DUMP TO PAPER TAPE

The Paper Tape Dump Routine can be employed to dump (a) the configured Configurator, (b) the configured Configurator and an unconfigured diagnostic, or (c) the configured Configurator and a configured diagnostic. The requirements are as follows:

- a. The paper tape loader must be specified during configuration as the diagnostic input device. The Configurator can therefore be loaded from any one of the specified input devices; the diagnostic, however, must be loaded from the paper tape reader. The Configurator must be configured manually.
- b. The dump device must be one of the following:
 - HP 2895, 2753 (punches)
 - HP 2752, 2754 (teleprinter tape punch device)
- c. The desired diagnostic should be loaded. It can also be configured. If a diagnostic is not loaded, only a copy of the Configurator Linkage Area, Utility Routines, and Drivers will be dumped to tape.

The Paper Tape Dump Routine flowchart is shown in figure 2-8.

NOTE:
If sequential execution of diagnostics has been selected and the diagnostic just loaded requires a configuration input an error halt (normally 102073) will be reached. Refer to the appropriate manual of diagnostics.

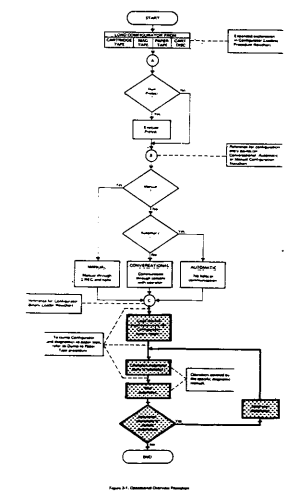

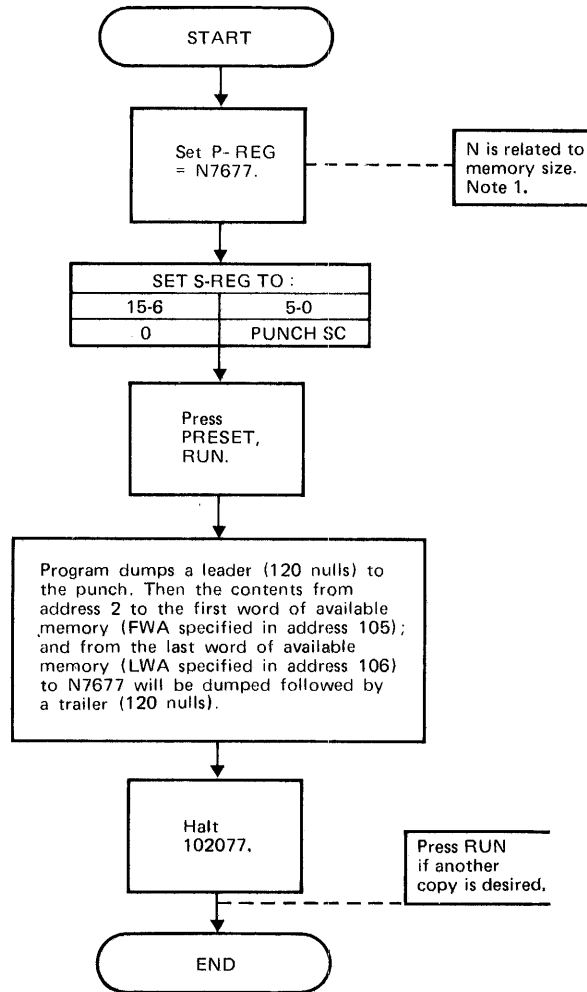

Figure 2-7. Configurator Binary Loader Flowchart

1. N=0 for 4K, 1 for 8K, 2 for 12K, 3 for 16K, 4 for 20K, 5 for 24K, 6 for 28K, and 7 for 32K.

Figure 2-8. Paper Tape Dump Routine Flowchart

3-1. GENERAL ORGANIZATION

The program is organized according to the memory map shown in figure 3-1. The map also includes the paragraph number that describes that area or function. The addresses shown in figure 3-1 are effective prior to configuration. Utility Routines and Configured Drivers are moved during configuration to the corresponding addresses in the last page of memory.

The area from 130 to N6477* may be overlaid when a diagnostic is loaded.

3-2. CONFIGURATOR LINKAGE AREA

This area, starting at address 100, is reserved by the Configurator for address links to utility routines and drivers. It also has data referenced by the diagnostic for computer parameters such as DMA/DCPC available, Memory Protect, memory size, etc. Refer to figure 3-2 for details of the linkage area.

When a diagnostic is loaded, it will overlay the JMP START (address 100), FWA (address 105), and DSN (address 126). The configurator loader does not protect the linkage area when a binary file is loaded.

The JMP START from address 100 establishes a common starting point for all diagnostics.

The FWA is the first unused memory location after the area occupied by the diagnostic. The area between the FWA and LWA is essentially unused memory. The LWA is established by the Configurator utility routines and is set to N6477 which is the last unused memory location before the routines. Some diagnostics use the area (FWA to LWA) as a buffer area. When dumping to paper tape, this area is not dumped; only locations 2 to FWA-1 and LWA+1 to N7677.

The DSN (Diagnostic Serial Number) is used to identify any diagnostic in memory. (See figure 3-3.) Each diagnostic is assigned a DSN when it is originally written and the revision number in the DSN is incremented each time the diagnostic is updated. The DSN allows the operator to check exactly what diagnostic and which revision of the diagnostic is loaded.

Any prereleased diagnostics or control programs will carry a pseudo-DSN of 177777. Figure 3-3 describes the DSN in detail. A diagnostic control program loads individual diagnostics, supplies parameters necessary for diagnostic execution, and/or monitors the sequential execution of discrete diagnostics.

*N is related to memory size. Also see figure 2-2, note 2.

3-3. PRETEST

The Pretest consists of a check to ensure that all major base set instructions work correctly. This is a cursory check and is not meant to replace any CPU Diagnostics. Each instruction is checked in a general manner and the entire base memory is checked with several patterns. When the Pretest passes, configuration can be performed with relative assurance that the basic computer is functional.

Four possible halts that can be encountered during the Pretest are as follows:

- a. When an error occurs (halt 102066) the operator must refer to the Pretest listing in appendix D. Any malfunctions must be corrected before continuing.

DESCRIPTION PARAGRAPH	STARTING MEMORY ADDRESS	FUNCTION
—	10	Trap cells for I/O select codes.
3-2	100	Configurator linkage area (figure 3-2).
3-3	130	Pretest part A.
	1400	Storage.
3-3	2000	Pretest part B.
3-4	3000	Establish computer parameters (memory size, DMA, MPRT, and computer type).
3-5		Configuration of drivers <ol style="list-style-type: none"> a. Console b. Line printer c. Diagnostic input device.
2-9		Manual configuration.
3-6		Table of drivers <ol style="list-style-type: none"> a. Consoles b. Line printers c. Diagnostic input devices.
3-7	N6500	Utility routines
3-14	N7000	Configured drivers <ol style="list-style-type: none"> a. Console driver b. Line printer driver c. Diagnostic input device driver.
	N7700	Basic Binary Loader (protected area or IBL).
<p>Note: The shaded area represents an area protected by the Configurator or an area within the BBL. An attempt to write into location N6500-N7777, when using the Configurator Binary Loader, will result in a halt 102055. Any programs loaded shall not overwrite the configurator linkage area (location 100-127), except locations, 100, 105, 116 and 126.</p>

Figure 3-2. Linkage Area

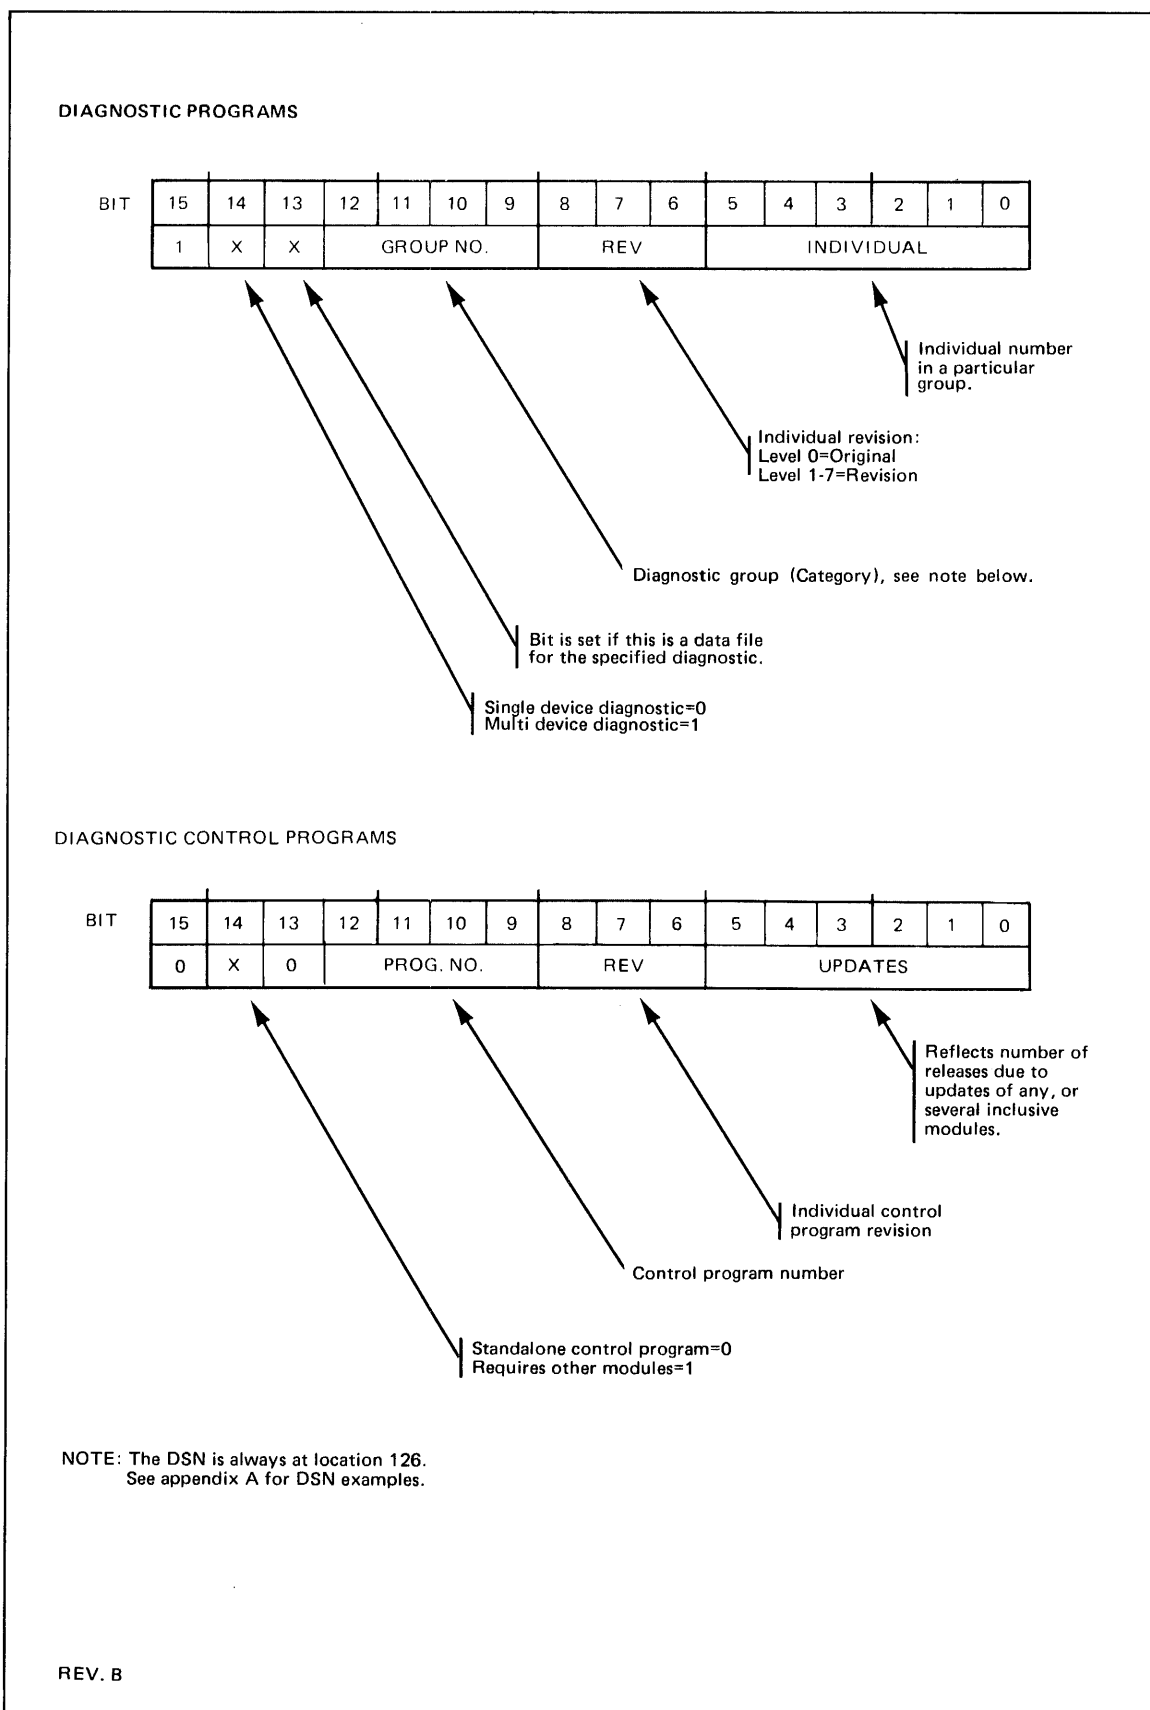

Figure 3-3. Diagnostic Serial Number (DSN)

- b. Halts 102020 and 102021 can occur only when testing a 2115 or 2116 computer where the S-Register cannot be modified under program control.
- c. Halt 102077 indicates successful Pretest execution.

3-4. COMPUTER PARAMETERS

The parameters calculated by the program are: computer type, DMA/DCPC, Memory Protect, and memory size. After being calculated, the computer type is used to look up the standard features, and the 1-millisecond timing constant. See figure 3-4 for computer type and options parameter details and figure 3-5 for memory size parameter details.

The calculated parameters are printed on the console device when Conversational Configuration is used. They are displayed in the A- and S-Registers when Manual Configuration is used. The display of parameters is for operator reference. If the parameters are wrong, it is a direct indication that the appropriate hardware has failed. The operator can correct the parameters by using Manual Configuration.

NOTES: * = ON EARLIER MODELS THIS WAS AN OPTION X = OPTIONAL FEATURE AVAILABLE ON INDICATED COMPUTER. 0 = FEATURE NOT AVAILABLE ON INDICATED COMPUTER. 1 = STANDARD FEATURE ON INDICATED COMPUTER.							
LINKAGE AREA , ADDRESS 115.							

Figure 3-4. Computer Type and Options

In determining the computer type, it should be noted that the Configurator cannot distinguish between a 2115 and 2116 computer. The program will default to a 2115 calculation if the calculated memory size is 8K or less.

The S-Register will flash to indicate a hardware problem if one exists when checking for MPRT. The operator must press HALT, PRESET, RUN.

3-5. CONFIGURATION OF DRIVERS

The device drivers are written in such a way that only the basic hardware differences (in programming for each device and interface) are kept in a table. One table is used for each driver (console line printer and diagnostic input device). When a device is specified, the appropriate driver is moved from the table to the driver area of the Configurator. During the move the select code is set to the one specified by the operator. If a cross link is specified, the program will only configure the driver that has been loaded into the driver area. Refer to paragraph C-10. If no device is specified, a pseudo-driver is used so that if the diagnostic calls that driver no action is taken. The select code in the base page is also cleared to indicate that there is no device for that driver. When using Conversational or Automatic Configuration, the Configurator program determines the console interface type installed in the select code specified by the operator. If the Configurator is unsuccessful in determining the interface type, the program will halt 102022. The operator must enter a new select code or use Manual Configuration.

If a line printer was not specified during configuration, a pseudo-driver is used to call the console output driver. Therefore, in the event the diagnostic calls the line printer driver, the message will appear on the console.

The Configurator program asks for the device model number of the diagnostic input device and the select code during configuration. This data is used to look up the Binary Loader driver.

MEMORY SIZE	15	14 13 12	11-0
4K	0	0 0 0	0
8K	0	0 0 1	0
12K	0	0 1 0	0
16K	0	0 1 1	0
20K	0	1 0 0	0
24K	0	1 0 1	0
28K	0	1 1 0	0
32K	0	1 1 1	0
LINKAGE AREA, ADDRESS 117.			

Figure 3-5. Memory Size

If the diagnostic input device model number cannot be found during input, the request line will be output repeatedly until a valid device number is entered. The same situation applies to the select code if the entry is greater than 77 or less than 10.

3-6. TABLE OF DRIVERS

The tables consist of console, line printer, and diagnostic input device drivers. The drivers in each table are written in a format that can be relocated to the driver routine area of memory during configuration. Primarily, the tables represent hardware differences (in programming) that must be known in order to interface with the driver routines.

The tables contain the following device drivers:

- a. Console:
 - 12531/12880
 - 12587
 - 12966
- b. Line printer:
 - 2767/9866
 - 2607/2610/2613/2614/2617/2618/2778
- c. Diagnostic Input Device:
 - Paper tape: 2737, 2748, 2758 (or teleprinter)
 - Magnetic tape: 7970B/E (9-track unit 0)
 - Cartridge disc: 7900/1 (unit 0, removable platter only)
 - Cartridge disc: 7905/20 (unit 0, removable platter, upper surface only)
 - Cartridge tape: 2644/2645 terminal

3-7. UTILITY ROUTINES

The following six paragraphs, listed below, describe the calling sequence for each of the Utility routines. The routines are generally required by diagnostics and are therefore incorporated in the configurator and are not overlaid by the diagnostic. These routines do not change the interrupt system and are interruptable at any point if the interrupt system is enabled.

- a. Timer or Wait Loop.
- b. S-REG Check.
- c. Decimal (Integer) to ASCII Conversion.
- d. Octal to ASCII Conversion.
- e. ASCII to Number (Binary) Conversion.
- f. Formatted Output.

The routines will not be directly used by the operator and are described here only to provide a broader scope of understanding the Configurator. The information can be used as a basis for creating individual diagnostics to run under the Configurator.

3-8. TIMER OR WAIT LOOP (ONE MILLISECOND)

CALLING SEQUENCE:

	LDA	TIME	NUMBER OF MILLISEC.
P	JSB	121B,I	GO TO TIMER
P+1	. . .		NORMAL RETURN
TIME	DEC	100	100 MILLISEC.

From P to P+1 = Time × 1 millisecond.

3-9. S-REGISTER CHECK

CALLING SEQUENCE:

	LDB	SW10	SWITCH NUMBER
P	JSB	122B,I	CHECK IT
P+1	. . .		RETURN IF SWITCH(ES) IS ON
P+2	. . .		RETURN IF SWITCH IS OFF
SW10	OCT	002000	S-REG BIT 10

Upon entry the B-register contains the mask for the switch(es) of interest. The return is P+2 if the switch is off (or all off) or P+1 if any switches in question are on.

3-10. DECIMAL TO ASCII CONVERSION

CALLING SEQUENCE:

	CLE		START WITH UPPER HALF (CCE=LOWER*)
	LDA	DECNO	GET NUMBER FOR CONVERSION
	LDB	BFPTR	GET LOCATION IN BUFFER TO STORE THE CONVERTED NUMBER
	JSB	123B,I	MAKE CONVERSION
	. . .		NORMAL RETURN
DECNO	DEC	-32000	DECIMAL VALUE
BFPTR	DEF	***	POINTER TO BUFFER

The above call will result in the following:

BFPTR	—	3	
	2	0	ASCII characters in memory.
	0	0	

Note: The routine does a right justify. The contents of the A- and B-Registers are lost.

3-11. OCTAL TO ASCII CONVERSION

CALLING SEQUENCE:

```

      CLE          START WITH UPPER HALF (CCE=LOWER*)
      LDA  OCTN    GET OCTAL NUMBER TO BE CONVERTED TO ASCII
      LDB  BFPTR   GET LOCATION IN BUFFER TO STORE THE
                   CONVERTED NUMBER
      JSB  124B,I  MAKE CONVERSION
      ...          NORMAL RETURN

      OCTN  OCT   034567

```

The above call will result in the following:

```

      BFPTR  0      3
            4      5      ASCII characters in memory.
            6      7

```

Note: The routine does a right justify. The contents of the A- and B-Registers are lost.

3-12. ASCII TO BINARY CONVERSION

Converts a decimal or octal ASCII coded number in memory to a binary number and puts it in the A-Register. This routine will accept ASCII numbers only, 60 to 70 (octal). Any other characters will terminate the conversion or the routine will terminate after converting the sixth character.

CALLING SEQUENCE:

```

      CLA          DECIMAL CONVERSION (CCA=OCTAL)
      LDB  BFPTR   GET LOCATION IN BUFFER TO STORE THE
                   CONVERTED NUMBER
      CLE          START WITH UPPER HALF (CCE=LOWER*)
      JSB  125B,I  MAKE CONVERSION
      ...          NORMAL RETURN
                   A-REG = CONVERTED NUMBER
                   B-REG = BUFFER ADDRESS OF NEXT CHARACTER
                   E-REG = UPPER/LOWER CHARACTER*

```

3-13. FORMATTED OUTPUT

To make it easier for programming, a simple format output call is available. This allows more room for the diagnostic.

*A four word buffer is required in this mode.

CALLING SEQUENCE:

CLA,	CLE (see note 1)	FORMAT STARTING
LDB	FMTA	POINTER TO FORMAT STRING
JSB	127B,I	CALL FOR OUTPUT
. . .		NORMAL RETURN
		A = 0 (OUTPUT COMPLETE)
		B = 0
		or
		A = 43 (# WAS REQUESTED)
		B = N.A.

```
FMTA  DEF  *+1
      ASC  7,FORMAT OUTPUT/
```

FORMAT CONTROL CHARACTERS

= NUMBER OUTPUT (See explanation — next page.)

/ = OUTPUT BUFFER WITH A CR-LF (OR PRINT IF OUTPUTTING TO LINE PRINTER)

← = OUTPUT BUFFER WITHOUT A CR-LF (OR SUPPRESS PRINT OF PENDING BUFFER, IF OUTPUTTING TO LINE PRINTER, UNTIL A /CONTROL CHARACTER IS ENCOUNTERED)

/ = or ← will cause a return with the original A- and B-REGS.

Note 1: CLA, CLE = OUTPUT TO CONSOLE
 CLA, CCE = OUTPUT TO LINE PRINTER

CALLING SEQUENCE: (number output)

This call can be used *only* in conjunction with the calling sequence above.

CCA	(see note 2)	OUTPUT NUMBER (OCTAL)
LDB	NMBR	GET NUMBER FOR OUTPUT
JSB	127B,I	CONTINUE FORMAT OUTPUT WITH NUMBER
. . .		RETURN

Note 2: CCA = OUTPUT NUMBER IN OCTAL
 CLA, INA = OUTPUT NUMER IN DECIMAL

If a call is made for a number output but a format has not been established, no action is taken and control is returned to P+ 1.

When the Format routine is started (A=0), the formatter moves each character in the string to a buffer. Each character is examined for the three control characters. If the character is #, a jump back to the caller is made. The program then indicates the type of conversion and passes the number back. The number is then converted and added to the buffer. The formatter will then continue to move each character until another control character is found. If the output string is larger than the format buffer, the buffer is output but no CR-LF or PRINT command is given. This process continues until a terminating control character is found (/ or ←).

*A four word buffer is required in this mode.

3-14. CONFIGURED DRIVERS

The following paragraphs (listed below) describe the calling sequence for each of the drivers (console, line printer, and diagnostic input device) available to the diagnostic program.

- a. Console Output.
- b. Console Input.
- c. Line Printer Output.
- d. Binary Loader.

3-15. CONSOLE OUTPUT

- a. Calling Sequence:

```

LDA  CNT      BUFFER COUNT
LDB  BUFA     BUFFER ADDRESS
JSB  102B,I   CALL CONSOLE OUTPUT DRIVER
      .       RETURN WHEN COMPLETE
      .       A + B MEANINGLESS

```

- b. Count and Address:

The count is the positive number of 8-bit characters in the buffer. The address is the absolute memory location of the first byte in the buffer.

Note: The count cannot be negative, the results are unpredictable. A buffer count of zero will issue a CR-LF to the console.

- c. Call Console Output Driver:

This call will initialize an output of the specified buffer. The buffer is unpacked 8 bits (1 byte) at a time and transferred to the console. When the transfer has reached the count, a carriage return (CR) line feed (LF) is issued and the driver returns to the caller. If, during a transfer, a RUBOUT character is found, the driver will return to the caller at that point regardless of the remaining count, and no carriage return or line feed is issued.

3-16. CONSOLE INPUT

- a. Calling Sequence:

```

LDA  CNTMX   MAXIMUM INPUT COUNT
LDB  BUFA    BUFFER ADDRESS
JSB  104B,I  CALL CONSOLE INPUT DRIVER
      .      RETURN WHEN COMPLETE
      .      A = NUMBER OF CHARACTERS INPUT BY THE
      .      OPERATOR
      .      B = MEANINGLESS

```

b. Count and Address:

The count is the positive maximum number of 8-bit characters to be input and loaded into the buffer. The address is the absolute memory location of the buffer.

Note: The count cannot be negative or zero, the results are unpredictable.

c. Call Console Input Driver:

This call will initialize an input from the console device. The characters will be put in the buffer in packed format (8-bit bytes) until the operator enters a CR (carriage return), or the buffer is filled.

Note: The driver automatically takes care of a RUBOUT (or delete) by the operator, issues a CR/LF, and resets the pointers to the start of the buffer. The driver requires only a CR to terminate an input.

d. Return:

When the operator enters a line feed, or the buffer is filled, the driver will return to the caller with the A-REG set to the input count.

3-17. LINE PRINTER OUTPUT

The same rules apply as for the Console Output driver except:

- a. The JSB is JSB 103B,I.
- b. A halt 106076 will occur if the line printer is not ready.

DIAGNOSTIC SERIAL NUMBERS

APPENDIX

A

Major groups are listed first (these are the prefixes for the DSN's). Specific DSN's follow this listing.

DSN	DIAGNOSTIC GROUP
000RXX	Control Programs
100RXX	Reserved
101RXX	CPU
102RXX	Memory
103RXX	Interface Cards
104RXX	Consoles
105RXX	Line Printers
106RXX	Tape Readers/Punches
107RXX	Plotters
110RXX	Reserved
111RXX	Discs
112RXX	Mag Tapes
113RXX	Card Readers
114RXX	Reserved
116RXX	Reserved
117RXX	Special Peripherals
177777	Prereleased program

Notes: See figure 3-3 in paragraph 3-2 for explanations.
R = revision.

All one's in the DSN represents a prereleased diagnostic or control program.

A diagnostic reference table is presented in table A-1, which lists the DSN's, diagnostic designations, part numbers, and date codes for the HP 2100 Series diagnostic media and the appropriate diagnostic reference manuals used with this Configurator.

Note: Part no. 24998-14002 consists of the 6 cartridge tapes 24998-13301, 24998-13302, 24998-13303, 24998-13304, 24998-13305 and 24998-13306 plus all manuals listed in the table.

*The diagnostics and control programs listed in this reference table are stored on the appropriate media in the sequence specified by the table. This does not imply that a specific system delivered to a user is compatible with all the hardware listed in this table.

CONFIGURATOR HALT CODE SUMMARY

APPENDIX

B

HALT CODE	REASON/RESPONSE
102000	<p>Manual Configuration was selected (S-REG originally cleared). The program is requesting the computer type and options. The program calculated type and options are stored in the A-REG and S-REG (S-REG only if the computer being used is a HP 21MX, 2100A/S or 2114A/B).</p> <p>Refer to figure 3-4 and paragraph 3-4 and if necessary, change the S-REG to the correct, or desired value and press RUN.</p>
102001	<p>Manual Configuration was selected (S-REG originally cleared). The program is requesting the console interface type and select code. The A-REG and S-REG are cleared by the program prior to the halt.</p> <p>Refer to figure 2-6 for the correct bit setting, set the S-REG accordingly and press RUN. If no console device is available ensure that the S-REG is cleared and then press RUN.</p>
102002	<p>Manual Configuration was selected (S-REG originally cleared). The program is requesting the line printer type and select code. The A-REG and S-REG are cleared prior to the halt.</p> <p>Refer to figure 2-6 for the correct bit setting, set the S-REG accordingly and press RUN. If no line printer is available ensure that the S-REG is cleared then press RUN.</p>
102003	<p>Manual Configuration was selected (S-REG originally cleared). The program is requesting the memory size. The program calculated size is stored in the A-REG and S-REG (S-REG only if the computer being used is a 21MX, 2100A/S or 2114A/B).</p> <p>Refer to figure 3-5 and paragraph 3-4 and if necessary, change the S-REG to correct, or desired value then press RUN.</p>
102004	<p>Manual Configuration was selected (S-REG originally cleared). The program is requesting the diagnostic input device type and select code. The A-REG and S-REG are cleared by the program prior to the halt.</p> <p>Refer to figure 2-6 for the correct bit setting, set the S-REG accordingly then press RUN.</p>
102010	<p>Illegal select code (<10) for diagnostic input device or console was chosen. Restart at P = 100 for configuration or P = 2 for Pretest.</p> <p>(If halt occurs during disc initialization, there was no console specified and program cannot be run.)</p>

HALT CODE	REASON/RESPONSE
102011	Checksum error during the loading of a binary file.
102020	Pretest halt for 2115 or 2116 computer. Set S-REG to 177777 and press RUN.
102021	Pretest halt for 2115 or 2116 computer. Clear S-REG and press RUN.
102022	Conversational or Automatic Configuration was selected and the console interface type could not be determined by the configurator from the select code input to the S-REG. Check the S-REG for the correct select code: a. Change it if incorrect, then press RUN. b. If the select code is correct check the interface type. If it is not a 12531, 12880, 12587, 12966 or 12968, no driver is available and no console can be specified. c. If the select code and type are correct there is a possible problem on the interface board and the Manual Configuration must be used. The diagnostic for the console or interface should be run.
102033	The disc boot has been loaded and executed. During execution the boot could not find the DMA/DCPC control word in upper memory (for the select code). Load A-REG bits 5-0 with the disc select code and press RUN.
102044	Disc did not respond with a flag. Restart program.
102045	Disc not ready or a hardware failure has occurred. Press RUN to try operation again.
102055	Address violation during the loading of a binary file.
102066	Pretest failed. Refer to M-REG for memory location in Pretest and appendix D for program listing.
102071	Manual Configuration was selected (S-REG originally cleared) and the console type input by the operator was not valid. a. To leave a pseudo-driver in place, press RUN or b. Restart configuration.
102072	An invalid loader type has been specified during configuration. a. Press RUN to leave a pseudo-loader in the driver area or b. Restart configuration.

HALT CODE

REASON/RESPONSE

102077	<p>End-of-operation.</p> <ol style="list-style-type: none"> a. Disc Boot. b. Disc Initialization. c. Paper Tape Dump. d. Load Complete. e. Configuration Complete (Manual). f. Pretest Complete.
106070	<p>“End-of-Files” was reached during a diagnostic load operation. The specified DSN was not found.</p> <p>If a different diagnostic(s) selection on the current tape is desired:</p> <ol style="list-style-type: none"> a. Load the A-REG with a new DSN. b. Clear the B-REG if sequential execution is not desired, otherwise set B-REG to appropriate sequential selection. c. Ready input device, set P-REG = 120, press PRESET and RUN. <p>If the diagnostic(s) originally selected is on a different tape:</p> <ol style="list-style-type: none"> a. Load the new tape. (If a 2644/45 cartridge tape, manually file forward over the configurator.) b. If sequential execution was selected ($B \neq 0$) set P-REG = N6500. c. Ready input device, press PRESET and RUN.
106071*	<p>No console was specified during configuration. A pseudo-driver was configured in place of the console driver and a request for input from the console was generated by the diagnostic.</p> <p>Press RUN to return to the program — but it should be noted that the request is in error. The program should check for the presence of a console (address 114 = SC of the console) before making a request.</p>
106072*	<p>No diagnostic input device was specified during Manual or Automatic configuration. A pseudo-driver was configured in place of the diagnostic input device driver and a request for input was generated by the diagnostic or the operator.</p> <p>No loading is possible.</p>

HALT CODE	REASON/RESPONSE
106073*	This halt has two meanings as follows: <ol style="list-style-type: none">During a transfer using the I/O processor loader link, an error was encountered. Restart the loader program in the I/O processor.The diagnostic memory size exceeded the available space. (Refer to paragraph 2-10c.)
106074*	Error on diagnostic input device (paper tape, magnetic tape, cartridge tape, or disc): <ol style="list-style-type: none">Device not ready; ready device: Press RUN.Time-out on long paper tape leader: Press RUN.Incorrect SC or device type specified: Reconfigure Configurator.Data error on device: Restart loader in Configurator by setting P = 120, A-REG to DSN, and B-REG to serial execution.
106075*	All unused memory locations in the first 4K are loaded with halts 106075.
106076*	An output request to the line printer has been generated and the line printer was not ready. Ready the line printer and press RUN.
106077*	Trap cell halt. M-REG = trap cell address.

*These halts can occur during diagnostic execution.

OPERATOR'S NOTES

APPENDIX

C

C-1. GENERAL

Appendix C is divided into four basic sections:

1. Figure C-1 gives the operator the basic instructions to transfer the Configurator and diagnostic(s) and/or control programs from one medium to another. It is a general guide to lead the user to the appropriate area in this manual (in case of paper tape dump or disc initialization), or to an operating system.
2. Magnetic tape and cartridge tape format required by basic loader and loader in Configurator.
3. Cartridge Disc Initialization for HP 7900/7901, HP 7905 and HP 7920.
4. Cross Link for program down-loading from a second computer in a multicomputer system.

LOAD CONFIGURATOR, DIAGNOSTIC(S), AND/OR CONTROL PROGRAM(S) FROM:	IF IT IS DESIRED TO TRANSFER THE CONFIGURATOR, DIAGNOSTIC(S), AND/OR CONTROL PROGRAMS TO:		
	PAPER TAPE	7970 MAG TAPE (9-TRACK) OR 2644/45 CARTRIDGE TAPE	7900/01 DISC 7905 DISC
Paper tape	Use Paper Tape Dump routine in Configurator; load Configurator and diagnostic from paper tape and create a memory dump of: a. Configured Configurator. — or — b. Configured Configurator and unconfigured diagnostic. — or — c. Configured Configurator and configured diagnostic.	Not possible with Configurator. Use DOS or RTE to transfer the absolute binary diagnostics onto magnetic tape or RTE to transfer the binary onto cartridge tape.	Use Disc Initialization Program to create a diagnostic disc with Configurator, desired diagnostic(s), and/or control program(s).
7970 Magnetic Tape (9-track) or 2644/45 Cartridge Tape.	Not possible with Configurator. Use DOS or RTE System for magnetic tape; use RTE System for cartridge tape.		
7900/01 Disc 7905 Disc 7920 Disc	Not possible due to special disc format.		

Figure C-1. Program Transfer Guide

C-2. MAGNETIC TAPE AND CARTRIDGE TAPE FORMAT

To facilitate the use of magnetic tape and cartridge tape, input drivers were added to the Configurator. This allows the operator to boot-in the Configurator, then load diagnostics using the Configurator driver. The Configurator, diagnostics, and control programs are in absolute binary format and the last file is followed by a second EOF record. To create a magnetic tape, the operator must use RTE or DOS to write the absolute binary programs onto magnetic tape. To create a cartridge tape, the operator must use RTE. Refer to figure C-2 for the format used on magnetic tape and cartridge tape.

C-3. CARTRIDGE DISC INITIALIZATION

C-4. GENERAL

The Cartridge Disc Initialization program is used to write first the Configurator, then Diagnostics and/or Control Programs on an HP 7900/1, HP 7905, or HP 7920 Cartridge Disc. After the Cartridge Disc has been initialized, the operator uses the Disc Loader (IBL or BMDL) to load the Configurator, then the Configurator is configured and used to load programs specified by a DSN from the disc.

The Disc Initialization program allows either the Configurator, diagnostics, and control programs to be coresident on a disc with an RTE or DOS operating system or have a disc entirely dedicated to diagnostic programs. When using the Disc Loader, the operator can specify via S-Register bit 3 to load either the Configurator (bit 3 set) or the system boot (bit 3 cleared), provided a system was on the disc prior to initialization. Disc Initialization requires continuous tracks on the disc. Track sparing is not employed by Disc Initialization. If diagnostics are coresident with a system, the system cannot do track sparing in the area where the diagnostic will be stored.

C-5. REQUIRED HARDWARE

The following hardware is required:

- a. An HP 2100 series computer with at least 4K of memory.
- b. An HP 7900/1, HP 7905, or HP 7920 Cartridge Disc. (Only computer type and cartridge disc type combinations specified by the appropriate hardware manuals are allowed to run Disc Initialization. The disc platter must be formatted and track sparing cannot be used. It cannot be the same physical disc as specified in paragraph C-5d.)

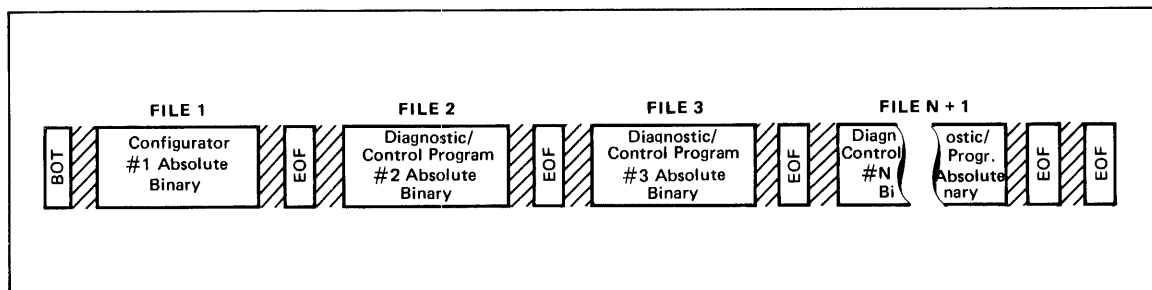

Figure C-2. Magnetic Tape and Cartridge Tape Format

- c. A console device for operator communication is required. The interface must be an HP 12531B/C/D, 12880A, 12587B, 12966A, or 12968A.
- d. A program input device as specified in paragraph 1-2d.

C-6. REQUIRED SOFTWARE

In addition to the Configurator and the programs to be loaded onto the disc, the Disc Initialization, part no. 24296-16002 is required.

C-7. OPERATING PROCEDURE

The operating procedures for Disc Initialization are outlined in figure C-3.

When the Disc Initialization program is executed it reads into memory cylinder 0, head 0, sector 0 where the system boot is located if the disc carries an operating system. It then copies data necessary for DOS IIIB, only that it saves the data so that the boot will operate with DOS IIIB.

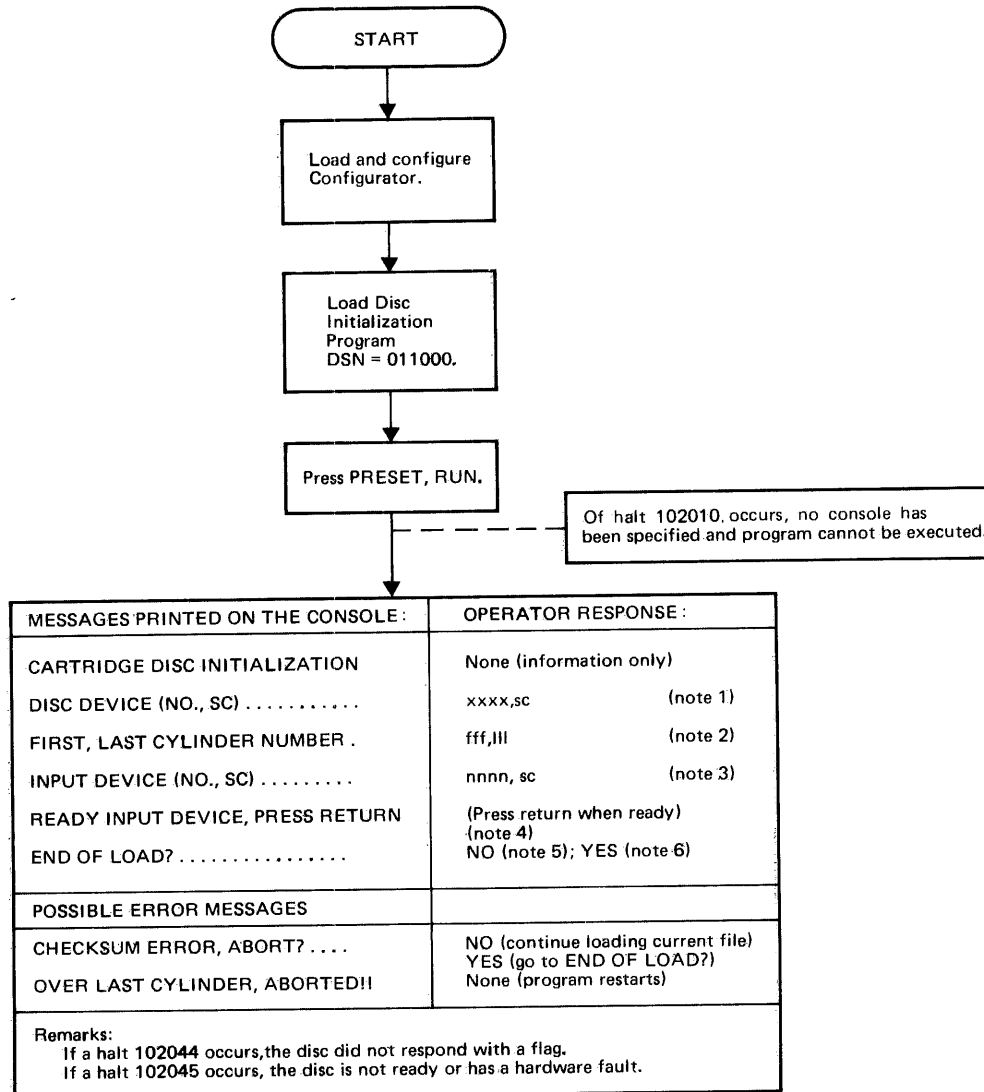

After the Configurator has been loaded and configured, and the Disc Initialization has been loaded with the help of the Configurator, the program (when executed) writes a title message and asks the operator to input the disc device type and SC followed by the first and last cylinder number. The numbers entered are first checked to ensure that the first cylinder number is smaller than the second and that the second cylinder number is not greater than 202 for 7900/1 or 410 for 7905/20. If either of the above conditions exists, the question is repeated. The Configurator loader routine is then written on the disc in the first cylinder specified by the operator. If the boot on the disc is not the original system boot but a previous Configurator boot, the program reads the original system boot from its previous location. The system boot is then written on the disc in the same cylinder as the loading routine.

The operator is then asked for the input device to be used. When the device is ready, the routine copies all files from the input device to the disc. The files must contain records of 60 words or less and be in absolute binary format. The files are stored consecutively until all files have been copied from the input device. At this point the operator is asked "END OF FILES?". If more files are to be loaded from the same input device, the operator answers "NO". If the entire file loading process is completed, the disc is ready to be employed as a diagnostic input device and the operator answers "YES" to terminate the disc initialization. If "RUN" is pressed after halt 102077, the program will restart.

C-8. CARTRIDGE DISC FORMAT

The first cylinder specified by the operator contains the original system boot and the Configurator loading routine. These are memory image formats. The Configurator (which must be loaded first), diagnostics, and/or control programs start on the next sequential cylinder and are in absolute binary format with the exception of the first three words. Each file starts on a sector boundary and the first three words contain the following:

- a. Word 1 = the cylinder number of the next consecutive file.
- b. Word 2 = the head and the sector of the next consecutive file.
- c. Word 3 = the highest memory address location used by the file.

- NOTES:
1. Respond with appropriate disc model number and lower SC (higher priority). XXXX = 7900, 7901, or 7905.
 2. Respond with cylinder number on disc to be used for program storage.
 3. Respond with the appropriate device number (or two letters) and select code.

nnn	= 2737, 2748 or 2758	Paper tape devices
	= 7970	Mag tape (9 - track only, Unit 0 only)
	= 7900 or 7901	Cartridge disc (removable platter only)
	= 7905	Cartridge disc (removable platter, upper surface)
	= 7920	Cartridge disc (upper surface)
	= 2644 or 2645	Cartridge tape
SC	= select code of device	(Lower SC in case of 2 SC)
 4. All binary files will be transferred from specified input device to disc until double end of files or end of tape is reached. The Configurator must be first file loaded.
 5. Respond with "NO" to continue loading more files from specified input device after input device has been readied.
 6. Respond with "YES" if end of load operation.

Figure C-3. Disc Initialization Flowchart

The last file is an end of files mark where:

- a. Word 1 = all one's.
- b. Word 2 = all zero's.
- c. Word 3 = all zero's.

C-9. DISC INITIALIZATION EXAMPLE

The system configuration is used for the following Disc Initialization example:

- a. HP 21MX Computer with DMA, MPRT, and 32K memory.
- b. Console in select code 12.
- c. Paper tape reader in select code 13.
- d. HP 7900A Disc in select code 15.
- e. HP 7970B Magnetic Tape Unit in select code 21.

Initialize a cartridge disc using magnetic tape as a source for the binary files. The cartridge disc can:

- a. Be blank (but must be formatted),
- b. Have a system on it with a reserved area set aside when the system was generated, or
- c. Have a system on it with an area set aside in the file area on disc. This area, once initialized, cannot be moved (example PK command). Therefore, it should be the first area in the directory. The area can be set aside by the ST,B command for DOS or the CR command for RTE. (A directory list will give the starting cylinder of the file.)

After the Disc Initialization program has been loaded by the Configurator and started at location 100, the following messages appear on the terminal:

```
CARTRIDGE DISC INITIALIZATION
DISC DEVICE (NO.,SC) . . . . . 7900,15
FIRST, LAST CYLINDER NUMBERS.0,40    (blank disc or the area set aside)
INPUT DEVICE (NO.,SC) . . 7970,21
READY INPUT DEVICE, PRESS RETURN
```

At this point the program loads the binary files sequentially from magnetic tape. When the transfer is complete, the program will output the message "END OF LOAD?". If more files are to be loaded from the same device, answer "NO". If all files are loaded and the cartridge is ready, answer "YES".

C-10. CROSS LINK

C-11. GENERAL

Cross Link is used in a multicomputer environment where one computer is designated as a central processor and all others are I/O (slave) processors. It is used to load the Configurator,

diagnostics, and control programs from the central processor to an I/O processor through one of three possible links:

- a. HP 12875 Processor Interconnect. (Four 12566 interfaces; Cross Link utilizes one 12566 processor interconnect pair.)
- b. HP 12665 Computer Serial Interface Kit.
- c. HP 12773 Computer Modem Interface Kit.

The two interface kits have the same program control. The differences are that the 12665 is hardwired and the 12773 is modem connected.

The program is useful when the I/O processor has one of the two links to the central processor but no input device and/or no console and/or no line printer attached, and a diagnostic has to be loaded and executed in the I/O processor. This does not imply that all three peripheral devices have to be attached to the central processor. However, when any one of the three devices are attached to the central processor, Cross Link must be loaded and execution started in the central processor so that the linkage for that device can be established to the I/O processor.

All drivers (input device, console, and line printer) which have been loaded as part of the Configurator will be configured to the peripherals in the central processor. The Cross Link program, which then is loaded, will link the drivers via link routines from the central processor to the I/O processor. This feature gives the user the capability to load a program (diagnostic) from the input device via the input device link in the main processor through the input device coupler driver in the I/O processor into the I/O processor memory. Then he starts program execution in the I/O processor. Message reporting to the console is done via the console coupler driver in the I/O processor, the console link and console driver in the central processor, and to the attached console. See figure C-4.

The Cross Link program does require the full dedication of the central processor because it is a standalone program. It is not possible to initialize a disc through Cross Link.

C-12. REQUIRED HARDWARE

The following hardware is required:

- a. Two or more 2100 series computers, each with at least 4K of memory.
- b. HP 12875 Processor Interconnect or HP 12665/12773 Computer Serial Interface. (Only computer type and Processor Interconnect combinations or computer type and Serial Interface combinations specified by the appropriate hardware manuals are allowed.)
- c. A console device for operator communication is optional. See paragraph 1-2c.
- d. A program input device as specified in paragraph 1-2d.

C-13. REQUIRED SOFTWARE

In addition to the Configurator and the programs to be cross-loaded to the I/O processor, the Diagnostic Cross Link, part no. 24296-16003, is required.

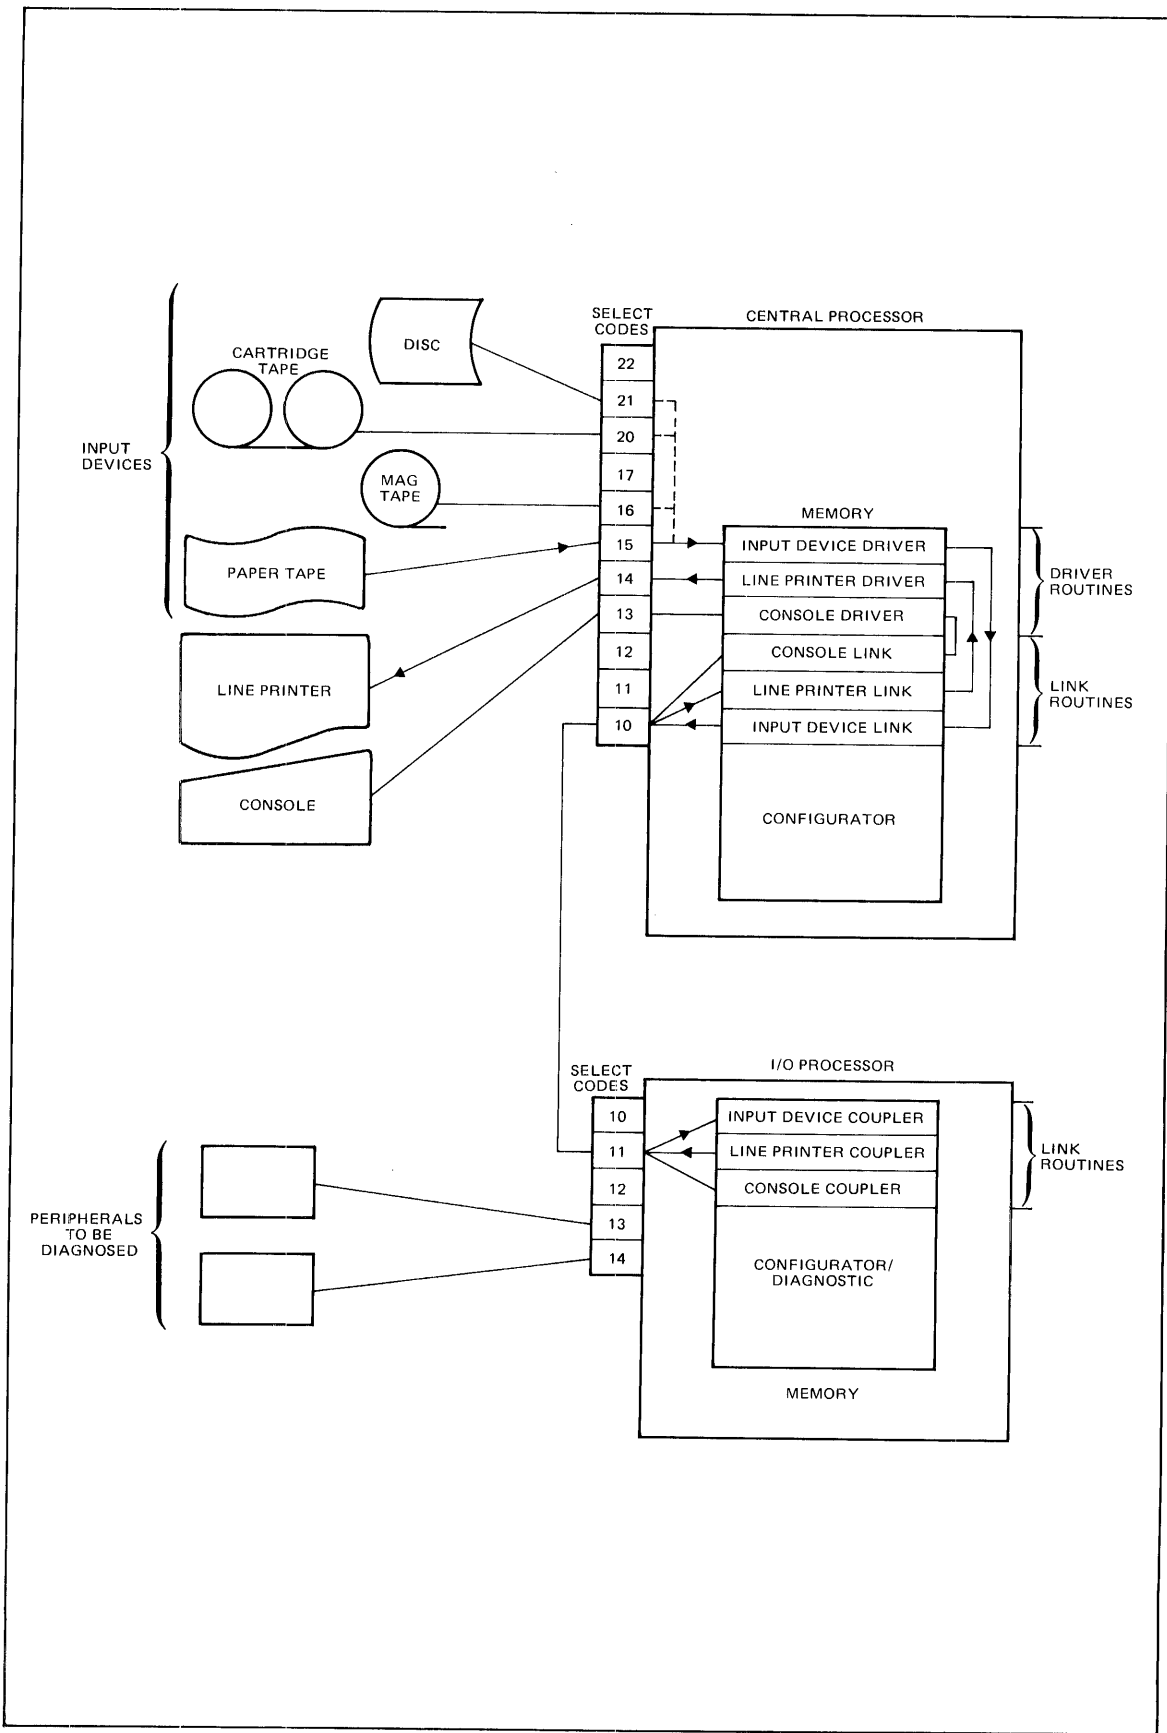

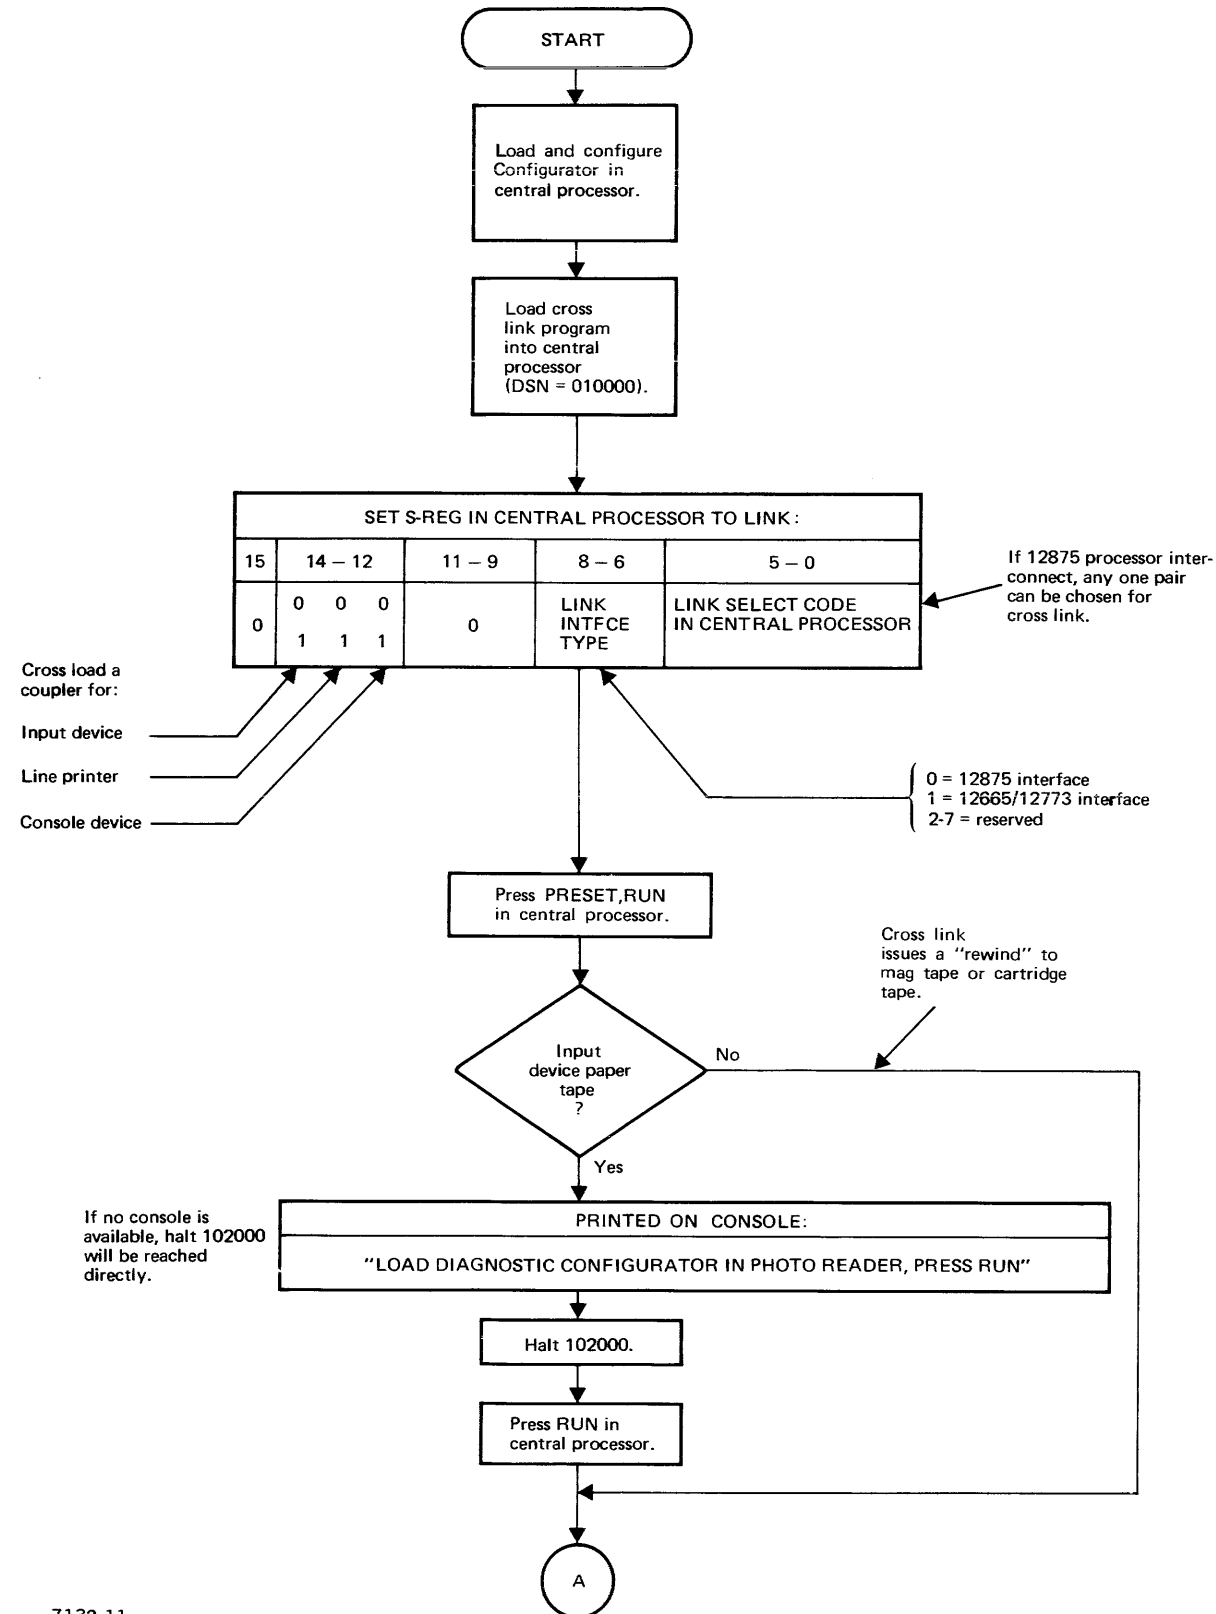

Figure C-4. Dual Computer Link

C-14. OPERATING PROCEDURES

The operating procedures for Cross Link are outlined in figure C-5. To execute the Cross Link program, the operator must first load and configure the Configurator in the central processor to the input device and/or console and/or line printer type and SC's, then load the Cross Link program with the Configurator. In S-Register bits 0-8, specify the link interface type and select codes and with S-Register bits 12-14, specify which drivers (input device, line printer, console) are to be used in the I/O processor. After pressing RUN on the central processor, the program instructs the operator to start the special binary loader* in the I/O processor to load the Configurator from the input device via the central processor to the I/O processor. When the Configurator is loaded, the Cross Link loads the couplers which were specified by the operator. It should be noted that the Cross Link program sets a flag in the I/O processor memory so that, when the Configurator in the I/O processor is configured, the program will use the console coupler (unless overridden by Manual Configuration). The input device coupler SC must be specified as the diagnostic input device during configuration of the Configurator. In case of a line printer, the first coupler SC must be specified.

*Special binary loader: for 12875 Processor Interconnect, standard Paper Tape Loader is employed to cross link.
for 12665/12773 Computer Interface Kit, SCE1 Loader Program, part no. 91700-16160 Rev. 1621, or equivalent ROM.

Cross load a coupler for:
Input device
Line printer
Console device

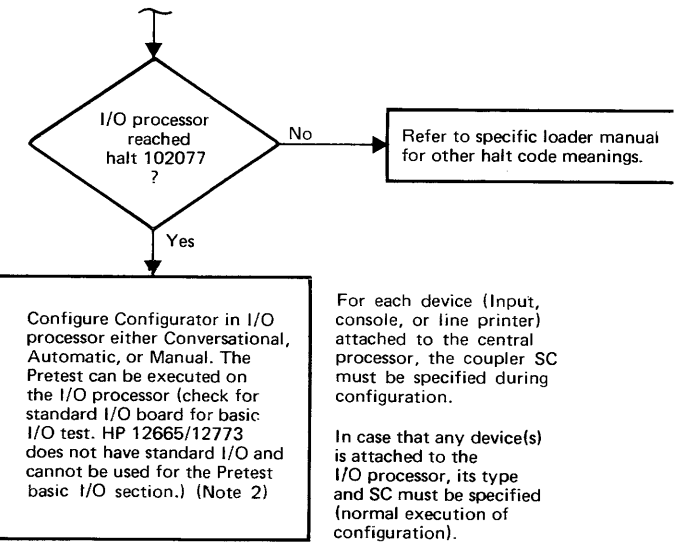

If 12875 processor interconnect, any one pair can be chosen for cross link.

Cross link issues a "rewind" to mag tape or cartridge tape.

If no console is available, halt 102000 will be reached directly.

When I/O processor is started, the link program down loads the Configurator and then the selected couplers. (Note 1.)

When the console SC is specified for Automatic or Conversational and a link has been cross loaded, the program will configure the link driver. This can be overridden by Manual configuration

- NOTES:
1. If an error occurs during cross loading, the program will output the message "CROSS LOAD ERROR (PRESS RUN TO START AGAIN)" and then halt 102060 is reached. When RUN is pressed, the program starts the Configurator loading process into the I/O processor again.
 2. If the link fails during configuration of the Configurator or executions of a diagnostic or control program, the program will output the message "CROSS LINK ERROR" and terminate the current operation and start checking for a new request.

BASIC BINARY LOADER LISTINGS

APPENDIX

E

E-1. GENERAL

With the availability of the Configurator and diagnostics on different media and the 2100A/S, 2114A/B, 2115A, and 2116A/B/C computers not having appropriate absolute binary ROM loaders, it will be necessary to toggle the corresponding loader into the last 64 locations of any one page in the available base memory, excluding pages 0, 1, or 2. (The configurator will load into any memory location from 2 to 7677.)

Table E-1 summarizes the four loaders listed in tables E-2 through E-5. Table E-1 also specifies the peripheral product and corresponding interface, subsystem, and loader format.

Table E-1. Basic Binary Loader Reference

LOADER LISTING	ASSOCIATED DEVICE			FORMAT
	PERIPHERAL PRODUCT	INTERFACE	SUBSYSTEM NUMBER	
Table E-2	7900 Cartridge Disc	13210A Disc Interface	12960A	Disc Boot
	7901 Cartridge Disc	13210A Disc Interface	12961A	Disc Boot
Table E-3	7905/20 Cartridge Disc	13175A or 13178B Disc Interface	12962A/B/C/D (For 7905 Only)	Disc Boot
Table E-4	2644/45 CRT Terminal	12966A Buffered Async Interface or 12968A Async Interface	N/A	Absolute Binary
Table E-5	7970B Mag Tape	13181A Mag Tape Interface	12970A	Absolute Binary
	7970E Mag Tape	13183A Mag Tape Interface	12972A	Absolute Binary

E-2. 7900/7901 DISC LOADER

This disc loader loads a program from an HP 7900 or 7901 into memory. Starting at the beginning of cylinder 0, it is used to load from the selected surface of disc drive 0 a block of 128 (decimal) words into memory starting at location 2011 (octal). It then jumps indirect to a subroutine via memory address 2055 (octal) to execute the program just loaded from the disc. This program can be a boot loader which loads the Configurator after RUN is pressed. If the load is not successful, the result is unpredictable and the disc loader may have to be reloaded if a second load execution is desired. Before execution, the S-register must be set to 10 (octal). Table E-2 lists the loading and execution procedure.

E-3. 7905/7920 DISC LOADER

This disc loader loads a program from an HP 7905 or an HP 7920 into memory. Starting at the beginning of cylinder 0, it is used to load from the selected surface of disc drive 0 a block of 128

words into memory starting at location 2011 (octal). It then jumps indirect to a subroutine via memory address 2055 (octal) to execute the program just loaded from the disc. This program can be a boot loader which loads the Configurator after RUN is pressed. If the load is not successful, the result is unpredictable and the disc loader may have to be reloaded if a second load execution is desired. Before execution, the S-register must be set to 10 (octal). Table E-3 lists the loading and execution procedure.

E-4. 2644/45 CARTRIDGE TAPE LOADER

This loader is used to load the Configurator stored on an HP 2644/45 cartridge tape via an HP 12966A Buffered Asynchronous Interface or an HP 12968A Asynchronous Interface into memory. The operator must select via the console the unit and file number prior to starting the loader. (Refer to *HP 2644A Mini Data Station Owner's Manual*, part no. 02644-90001, or to the *HP 2645A Display Station User's Manual*, part no. 02645-90001.) There are no S-register settings required. Table E-4 lists the loading and execution procedure.

E-5. 7970B/7970E MAGNETIC TAPE LOADER

This loader is used to load the Configurator from 9-track magnetic tape (unit 0 only) into memory. Due to the fact that this loader does not have file selection capabilities, it is the responsibility of the operator to ensure that the next file to be read is the Configurator. There are no S-register settings required. Table E-5 lists the loading and execution procedure.
