| 70017 | Automatic Sampler | 73255-73750 |
| 70020 | ----- | |
| 70021 | ----- | |
| 70036 | Common Exit | |

PROGRAMMING AND OPERATION CONVENTIONS

I. Drum Image of HSS:

Drum cells 76000-77777 are reserved for the image of 00000-01777 of HSS. This image is used by most service routines as temporary storage for part of HSS while the service routine operates from HSS. The programmer is advised not to load into the image as this may result in incorrect loading of HSS. The programmer may use this part of drum storage as a temporary pool or work space during the operation of his program, but in so doing deprives himself of the use of Changed Word Post-Mortem.

II. Drum Storage for the Service Library

Drum cells 70000-75700 are reserved for the Service Library and are not, in general, available for program use. Loading programs into the range 70000-70037 deprives the programmer of all facilities of the Service Library, while loading into the range 70040-75777 may deprive him of only part of the Service Library.

COMMENTS ON USE OF SERVICE LIBRARY

I. Paper Tape Preparation

- a) Biocotal tapes should have two 7th level punches at the very end of the tape.
- b) Flex code (absolute) program tapes should have at least one 7th level punch at the very end.
- c) Flex dump tapes are suitable for reloading via Flexie. Be sure that a 7th level punch is present at the end of the tape.

II. Loading Routines "Transfer Control" Option

Both loading routines have a "transfer control" option. The following procedure will effect the transfer for either load routine.

- (1) Set program tape in reader
- (2) MASTER CLEAR
- (3) Set the computer on MAIN PULSE ϕ .
- (4) Manually insert the following into PCR

37 70036 70001 (2)

- (5) Set PAK = program start
- (6) START.

PROGRAM ENTRIES TO SERVICE ROUTINES

The block of cells 70000-70037 is reserved for entries to the service routines. Cell 70036 is reserved as the common exit from those service routines which by their nature admit program entry and exit. For example, the use of the Biocatal Loading Routine as a subroutine would be effected by the instruction 37 70036 70001. All required parameter words must be placed in the appropriate registers before entry is made to the particular service routine by a Return Jump instruction. For example, the use of the Biocatal Dump would be effected by the following sequence:

```
n: 11 (x) 31000
n+1: 37 70036 70006
n+2: -- -----
```

where, say (x) = 00 00001 01777

CAUTION: Since the service routines each have only one entry, any inadvertent (or not) loading in the range 70000-70037 deprives one of all the service routines.

SERVICE ROUTINES

Biocatal Loading Routine

The routine will load anywhere. Loading into HSS and 76000-77777 can result in incorrect loading of HSS. A sum check is made whenever the input tape contains an insert to 75202, followed by a double precision check sum and a check address of 75204. Note: cells 75202 and 75203 will not be loaded with the sum.

Operating Instructions:

- (1) Set PAK = 70001; START.
- (2) Computer halts on 56 00000 70001 after completing read in. START to load another tape.
- (3) Two consecutive seven-level punches in the trailer should be present. If these punches are not present, the following procedure may be used: FORCE STOP after the paper tape has passed through the reader, MASTER CLEAR, START at 00032. The last block of information read in is then stored in its proper location.
- (4) Errors
 - (a) Machine prints "t" and halts. The loading routine is not in HSS correctly and must be restored. START causes another transfer to HSS. If the check fails again, reload the service library onto MD.
 - (b) Machine prints "c" and halts. A check address has failed. STARTing ignores this error and routine proceeds as though error had not occurred. A check address failure should not be ignored as it is very likely that the paper tape is in error.
 - (c) Machine prints "m" and halts. Check sum has failed to agree with computed sum of data read in. START to ignore this error and continue loading.

Flex Code Loading Routine

This routine is designed to load Flex Code tape prepared on a Flexowriter in the conventional fashion for translating to biocatal. It operated in the same fashion as the biocatal loading Routine. A sum check is made whenever the input tape contains an insert to 75202, 75203. (See above).

Operating Instructions:

- (1) Set PAK = 70002; START
- (2) Computer halts on 56 00000 70002 after completing read in. START to load another tape.
- (3) At least one seven-level punch should be present in the trailer to stop the routine. If this punch is not present, the following procedure may be used.
 - (a) FORCE STOP after the paper tape has passed through the reader.
 - (b) MASTER CLEAR; set PAK = 00025; START.
- (4) Errors:
 - (a) Machine prints "t" and halts. The loading routine is not in HSS correctly and must be restored. START causes another transfer to HSS. If the check fails again, reload the service library onto MD.
 - (b) Machine prints "c" and halts. A check address has failed. A START ignores this error and routine proceeds as if no error had occurred.
 - (c) Machine prints "m" and halts. A check sum has failed to agree with computed sum of data read in. START to ignore the error.

Flex Dump

This routine dumps the contents of consecutive storage cells on punched paper tape only. Automatic page editing is provided and every eighth address is given. The punched tape is suitable for re-loading via the Flex Code loading routine. A check sum is punched out at the end of the dump. (A_L), (A_R), (Q) are not restored or punched out. HSS is restored.

Operating Instructions:

- (1) Enter in Q_u the address of the first cell to be dumped.
Enter in Q_v the address of the last cell to be dumped.
If a seven-level punch stop code is desired at the end of the dump set Q₃₅=1.
- (2) Turn ON the High Speed Punch.
- (3) Set PAK = 70005; START.
- (4) The machine halts on 56 00000 70005 providing a re-entry for another dump.
- (5) Errors:
 - (a) Machine prints "t" and halts. The dump routine is not in HSS

correctly. START causes another transfer to HSS. If the check fails again, reload the service library onto MD.

(b) Machine prints "p" and halts. An illegal parameter word has been set up in Q and is displayed there. Clear Q manually and insert correct parameter; START

(6) This routine dumps only one tape of storage at a time, either HSS or drum. 76000 to 76314 is used as an image region for 00000 to 00314.

Biocatal Dump

This routine will dump onto paper tape in biocatal form the contents of any specified number up to 7777_g of consecutive storage cells in HSS or the drum except 76000-77777. A check sum is automatically punched at the end of the dump. A double seven-level punch at the end of the tape is optional.

Operating Instructions:

- (1) Enter in Q_u the address of the first cell to be dumped.
Enter in Q_v the address of the last cell to be dumped.
If a double seven-level stop code is to be punched following this dump, set $Q_{35} = 1$.
- (2) Turn High Speed Punch ON.
- (3) Set PAK = 70006; START.
- (4) The stop at the end of the dump, 56 00000 70006, provides a re-entry for another dump. The contents of A and Q are not retained. HSS is restored at the end of the routine.

Changed Word Post Mortem

This routine is designed to compare the contents of 00000 to 01777 of HSS with its image at 76000-77777. The image contains (unless disturbed) the original contents of HSS as read into the computer. Those words in HSS which have been changed by the execution of the program are the only ones reported out.

Operating Instructions:

- (1) Turn High Speed Punch ON.
- (2) Set PAK = 70013; START.
- (3) Compare halts on 56 00000 70013.

The following will be punched in Flex Code.

- a) (Q)
- b) (A_R)
- c) (A_L)
- d) Any changed word according to the following:

| HSS word | Image word | HSS address |
|----------|------------|-------------|
|----------|------------|-------------|

At the end of the routing, (A), (Q) and HSS are restored.

- (4) This routine uses the cells 74740-75137 as temporary storage for part of HSS while the routine operates.

Single Breakpoint Stop

This routine permits one to select a single address of a program which one can run on high speed and stop before executing the instruction at that address. One may then sample the results of computation to date or step through several instructions. Restriction: the breakpoint instruction must be one which is not modified by the program.

Operating Instructions:

- (1) enter in Q_v the breakpoint address.
enter in A_v the entry address for the program.
- (2) Set PAK = 70016; START. The program will be executed up to the breakpoint at which time the computer will halt on 56 00000 70016, providing a re-entry for another breakpoint stop.

Automatic Sampler (Sam-0)

This routine provides for the printing or punching (in octal or decimal) the contents of any selected cells at selected check points. Output is suppressed for the first N_p times through the check point and after $(N_p + N_s)$ times. The program which is being sampled is executed normally between check points. It is not necessary to provide for sampling while writing the program. The programmer stores in any available block of memory a list of information regarding check points, cells to be sampled, or scales.

A) Operating Instructions:

- (1) Read in the program to be sampled. This is the unmodified problem program.
- (2) Read in the "Sampling List Tape". See below for description of this tape.
- (3) Set PAK = 70017 START. The routine sets up check points and transfers control to α which is contained in the sampling list.

B) Sampling List Tape (Flex or Biocatal).

This tape loads cell 73643 and the sampling list which contains

a number of sublists, one for each check point. Each sublist contains all information necessary for sampling at one check point. This information may be stored in any convenient set of consecutive HSS or MD cells except 00100 through 00167.

The sampling list tape format is as follows:

| Fixed Storage | 73643 | XX | L_0 | L_F |
|---------------------|-------|----|-------|-------|
| Check point address | L_0 | 00 | 00000 | c.p. |
| Index Word | L_1 | 00 | N_p | N_s |
| Parameter words | L_2 | 0a | M_p | s |
| | . | .0 | . | . |
| | . | . | . | . |
| | . | 0a | M | s |
| End word | . | 70 | 00000 | 00000 |
| End word | . | 70 | 00000 | 00000 |
| | . | 00 | 00000 | c.p. |
| | . | 00 | N_p | N_s |
| | . | 0a | M_p | s |
| | . | . | . | . |
| | . | . | . | . |
| | . | 70 | 00000 | 00000 |
| | L_F | 70 | 00000 | 00000 |

one complete sublist

- (1) Fixed storage - The word XX L_0 L_F read into 73643, gives the address of the first cell (L_0) and the last cell (L_F) of the sampling list. Printing or punching is specified by XX, 61 for printing and 63 for punching.
- (2) Check point address - The word 00 00000 c.p. gives the check point address, c.p. Sampling occurs before execution of the instruction at c.p.
- (3) Index word - The word 00 N_p N_s gives two 5-octal-digit numbers, N_p , signifying the number of times the check point is to be passed before sampling starts, and N_s , the number of times sampling is to occur at the check point.

- (4) Parameter words - These are of the form $Oa M s$ where the first octal digit is always zero. The second octal digit, a , takes on the values

0 for octal output
1 for decimal output.

If $a > 1$, the parameter word is ignored. The u -portion of each parameter word contains the octal address, M , of a cell whose contents are to be sampled. If $M = 32001$, (A_1) is sampled. If M is not a machine address the parameter word is ignored. The v -portion of each parameter word contains the binary scale factor, s , of the contents of M . $0 \leq s < 70$. If $s \geq 70$, "2 small" is printed.

- (5) End words - The last two words of each sublist are of the form 70 00000 00000 with the exception of the second end word of the last sublist (L_f), which is 70 00000 \sphericalangle . SAM-0 jumps to \sphericalangle after setting up check points on a 70017 start.

C) Output

Shown below is an example of sampler output where the check point address was 00303.

| | |
|-------|----------------|
| 00303 | |
| 00075 | 12 34567 12340 |
| 00076 | 77 03124 65432 |
| 00100 | 1.23456789017 |
| 00101 | -321.098632812 |
| 00102 | 993059913.000 |
| 00103 | 0.43210987653 |
| 32001 | 14 00000 00000 |
| 31000 | 37 37373 73737 |

D) Restrictions

- (1) The word initially stored at a check point must be an

instruction; it must not be a repeat command or a repeated instruction and it may not be written into or out of at any time during the course of the program.

- (2) The Sampling List Tape must not load into cells 01777 or 02000, i.e., it must be on one side or the other of this point.

APPENDIX

Paper Tape Loading Routines

Introduction

Paper tape is described as being divided into rows and columns: a single column of positions across the width of a tape is called a frame. Frames are divided parallel to the length of the tape into seven levels. Six of these levels are used primarily to represent information to be placed in computer storage, while the seventh level is used to represent loading directions. A hole punched in any of the six data levels of the tape represents a one, while the absence of a hole represents a zero.

Words punched onto paper tape are of three kinds: enter data words, insert address words, and check address words. Enter data words are those which contain information to be stored internally by the computer, while insert address words and check address words are used only for loading purposes. The insert address contains the address at which the first data word of a block of consecutive data words is to be stored, while the check address contains the address plus one at which the last data word has been stored.

For a check sum of data on the tape, the following four words should appear on the tape after the data to which the sum applies:

1. Insert address 75202
2. High order of 36 bits of check sum
3. Low order of 36 bits of check sum
4. Check address 75204

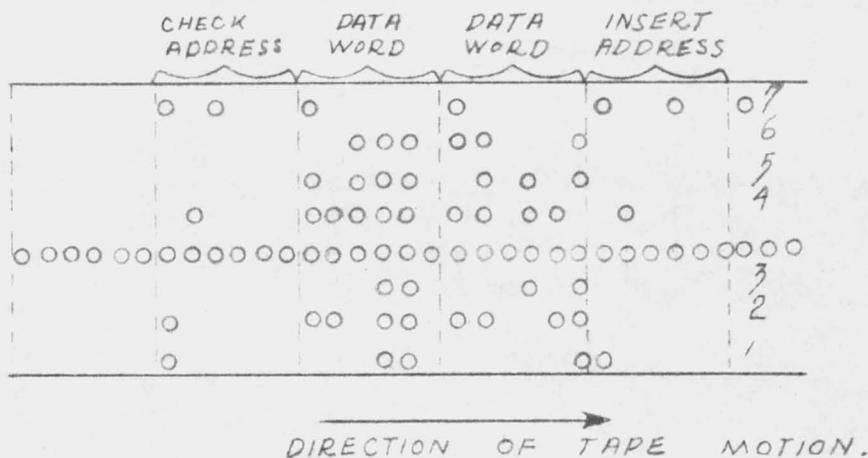

The check sum must be the sum of all the data on the tape following the preceding check sum. The check sum will not be loaded into 75202 and 75203. These words will be left undisturbed. Since a check sum test is performed whenever a check address of 75204 is encountered, 75204 should not be used for any other check address.

Biocatal Loading Routine

Words containing 12 octal digits each are punched onto bi-octal tape two digits to a frame. Thus, six frames of tape are necessary to represent one bi-octal coded word. When the bi-octal loading routine is used, the three kinds of words described above are distinguished by the frames in which seventh level holes are located. Each enter data word must have a seventh level hole

in the sixth frame. Insert address words and check address words also have seventh level-holes in the sixth frame, but in addition, the insert address has one in the third frame and the check address has one in the fourth frame. Furthermore, should there be a gap on the tape between the two blocks, a seventh level hole must be punched in the frame directly preceding the first frame of the next insert address word on the tape. This also applies to the very first block of data on the tape. The tape should always begin with an unpunched leader of about 10 inches, and should end with an unpunched trailer of about the same length. A seven level punch in any two consecutive frames of the trailer directs the Biocatal Loader routine to store the data read in thus far, transfer the location 76000-77777 to 00000-01777, and come to a programmed stop.

The following is a diagram of a tape bearing the two data words 671234007252 and 00777701232, which are to be stored at address 01001 and 01002 respectively.

Flex Code Loading Routine

Input tapes using this loader are usually prepared directly from the electric typewriter (Flexowriter) in coded form, one character to a frame. In order to obtain a correct loading format, it is important that periods be used only in standard positions.

Each data word must consist of twelve octal digits between two periods. These twelve digits are grouped as follows: two digits followed by a space, five digits followed by a space, and the last five digits followed by a period and carriage return. Insert and check addresses also consist of twelve digits but have periods and digit groupings that are peculiar to each. An insert address reading from left to right is composed of a period, six zero digits, a period, a zero, and a five digit address followed by a period and carriage return. A check address is grouped from left to right as follows: seven zero digits, the most significant digit of a five digit address, a period and the remaining four digits of the address followed by a period and carriage return.

Example:

| | | |
|----------------|-----------------|------------------------------------|
| Insert address | .000000.076050. | (address of first data word) |
| Data word | 00 00400 00500. | |
| Check address | 00000007.6051. | (address following last data word) |

Incorrect word format will result in that word not being interpreted correctly, or not being stored in its proper location. Errors of this type will usually show up as check address failures.

One seven level punch should be used at the end of the tape after the last check address to stop the reader and complete the routine. There should be no other seven level punch since any such punch will halt the reader regardless of its position on the tape.

SUBJECT: APL Complex Arithmetic Package
(Not a standard USE routine)

This subroutine converts the LLO3A temporarily to a machine with three-address logic, separate storage for instructions and data, working on complex floating point numbers. At each entry it can handle interpretive programs containing up to 512 instructions and up to 512 data.

The data are in the form $Z = x + iy$, where x and y are standard LLO3AF floating point numbers and are stored in two successive machine storage cells.

The instructions are in the form

op L ABC,

where op is a 2-octal-digit operation code, L is an address modification index of 1 octal digit, and A, B, C are each 3 octal digits indicating instruction addresses, data addresses, or integers, according to the operation code. Each instruction therefore consists of 12 octal digits and can be stored in one machine storage cell.

If u is the actual machine address of the first cell used for data storage and v is the actual machine address of the first cell used for instruction storage, then the relation between machine addresses and pseudo-addresses is as follows:

| <u>Data</u> | <u>Instructions</u> |
|---------------|---------------------|
| $u + 0$ } 000 | $v + 0$ 000 |
| $u + 1$ } 001 | $v + 1$ 001 |
| $u + 2$ } 001 | $v + 2$ 002 |
| $u + 3$ } 002 | etc. |
| $u + 4$ } 002 | |
| $u + 5$ } 002 | |
| etc. | |

The instruction stored at instruction address 000 (i.e. at machine address v) is the first one executed when the complex arithmetic package is called in by writing

RJ R L016
00 u v
NI

The pseudo-instructions

- 00 0 000 000 000 Leave the interpretive system and execute NI in basic machine language.
- 01 L A B C Perform the operation indicated by the code A upon the contents of data address B and store the result at data address C. (See Table 1)
- 02 L A B C Add the contents of data address A to the contents of data address B and store in data address C.
- 03 L A B C Subtract the contents of data address B from the contents of data address A and store in data address C.
- 04 L A B C Multiply the contents of data address A by the contents of data address B and store in data address C.
- 05 L A B C Multiply the contents of data address A by the contents of data address B, reverse the sign of the product, and store in data address C.
- 06 L A B C Divide the contents of data address A by the contents of data address B and store in data address C.
- 07 L A B C Set the contents of data addresses A, B, and C equal to zero.
- 10 L A B C Here A is an integer. Transfer A consecutive data from the block starting at data address B to the block starting at data address C. In case the two blocks overlap, no datum is overwritten until after it has been transferred.
- 11 L A B C Here A is an integer. Transfer A consecutive instructions from the block starting at instruction address B to the block starting at instruction address C. In case the two blocks overlap, no instruction is overwritten until after it has been transferred.
- 12 L 000 000 C Transfer control to instruction address C.
- 13 L A B C Put the three octal digits A in the C-address portion of the instruction at address B and transfer control to instruction address C.
- 14 L A B C Put the three octal digits A in that portion of the instruction at address C which is indicated (see Table 2) by the code B.

- 15 L A B C Add the integer A to that portion of the instruction at address C which is indicated (see Table 2) by the code B.
- 16 L A B C Subtract the integer A from that portion of the instruction at address C which is indicated (see Table 2) by the code B.
- 17 L A B C Here A and B are integers and C is an instruction address. Add one to A. If then $A < B$ jump to instruction C. If, however, $A \geq B$ then subtract B from all those addresses (in all instructions from the C-th to the one preceding this one) which were modified as a result of an L-code different from zero. Then set $A=000$ and take next instruction.
- 20 L A B C If the contents of data address A are less in absolute value than the contents of data address B then transfer control to instruction address C; otherwise take next instruction.
- 21 L A B C If the real part of the contents of data address A is negative, transfer control to instruction address B; otherwise transfer control to instruction address C.
- 22 L A B C If the imaginary part of the contents of data address A is negative, transfer control to instruction address B; otherwise transfer control to instruction address C.

The L-code

The L-code of three bits in each instruction permits any of the addresses in that instruction to be increased by one each time the instruction is carried out, as described in Table 3. This increase of addresses is done after the operation is carried out but before going on to the next instruction.

The L-code for each instruction, together with the loop instruction 17LABC, provides a very simple and surprisingly versatile method for coding loops. The following almost trivial example may help to indicate how the coding might go in more complicated and more interesting cases. It shows, in particular, that loops within loops can be handled with a minimum of step and reset operations.

Example
$$y = \sum_{i=1}^5 a_i \sum_{j=1}^i b_{ij} x_j$$

Data address

| | |
|---------|--------------------------------|
| 100-104 | x_1-x_5 |
| 105 | b_{11} |
| 106-107 | $b_{21}-b_{22}$ |
| 110-112 | $b_{31}-b_{33}$ |
| 113-116 | $b_{41}-b_{44}$ |
| 117-123 | $b_{51}-b_{55}$ |
| 124-130 | a_1-a_5 |
| 131 | $b_{ij} x_j$ |
| 132 | $\sum b_{ij} x_j$ |
| 133 | $a_i \sum b_{ij} x_j$ |
| 134 | $\sum a_i \sum b_{ij} x_j = y$ |

| <u>Instruction address</u> | <u>op</u> | <u>L</u> | <u>A</u> | <u>B</u> | <u>C</u> | <u>comment</u> |
|----------------------------|-----------|----------|----------|----------|----------|--|
| 100 | 14 | 0 | 105 | 100 | 103 | reset b_{ij} |
| 101 | 07 | 0 | 134 | 134 | 134 | clear 134 |
| 102 | 07 | 0 | 132 | 132 | 132 | clear 132 |
| 103 | 04 | 6 | 105 | 100 | 131 | $b_{ij} x_j \rightarrow 131$ |
| 104 | 02 | 0 | 131 | 132 | 132 | $\sum b_{ij} x_j \rightarrow 132$ |
| 105 | 17 | 2 | 000 | 001 | 103 | loop |
| 106 | 04 | 4 | 124 | 132 | 133 | $a_i \sum b_{ij} x_j \rightarrow 133$ |
| 107 | 02 | 0 | 133 | 134 | 134 | $\sum a_i \sum b_{ij} x_j \rightarrow 134$ |
| 110 | 15 | 4 | 001 | 100 | 103 | step b_{ij} |
| 111 | 17 | 0 | 000 | 005 | 102 | loop |

Relation to USE program

The subroutine here described is being coded in a form somewhat different from the USE standard form for local convenience. It will be noticed, for example, that the parameter word `OO u v` is put after the return jump used to call in the subroutine rather than, for instance, in the accumulator; this can of course easily be changed if desired. The other departures from standard (such as use of local sub-subroutines for mathematical functions, etc.) are in much the same category now that the standard compiler permits subroutines to call in other subroutines. In short, the conversion to standard USE form could easily be made if the organization wanted it done.

The logical portion of the subroutine, which interprets the operation codes and does the housekeeping, has purposely been kept separate from the mathematical portion, which actually does the addition, subtraction, etc. This was done so that the same logical portion could serve for different arithmetics, such as real floating point double precision, real stated point double precision, complex double precision, matrix arithmetic, etc., as the required mathematical coding for the several operations becomes available. The advantage of a common logic for these various kinds of arithmetics needs no insistence.

If USE decides not to include this among the standard routines, the coding in present form will be made available (when checked out) to any individual members upon request. In any event, APL will welcome suggestions and criticisms.

Acknowledgement

The debt owed by the present routine to the interpretive system devised by Bell Telephone Laboratories for the IBM 650 (see IBM Tech. Newsletter No. 11) will be obvious to those who are familiar with that system, and is hereby brought to the attention of those who are not.

Table 1: Operations performed by OLLABC

| <u>A</u> | <u>Operation performed on contents of B</u> |
|----------|---|
| 000 | absolute value |
| 001 | exponential |
| 002 | logarithm (principal value) |
| 003 | conversion rectangular to polar form |
| 004 | conversion polar to rectangular form |
| 005 | multiply by -1. |

Table 2: B-codes for operations 14, 15, 16

| <u>B (octal)</u> | <u>Portions of instruction C which are modified</u> |
|------------------|---|
| 000 | none |
| 001 | C address |
| 010 | B address |
| 011 | B and C addresses |
| 100 | A address |
| 101 | A and C addresses |

Subject: Preliminary Information on the
Content of Registers
Execution Times
for the 1103A Floating Point Instructions (RR)

PRELIMINARY INFORMATION
ON THE
CONTENT OF REGISTERS OF THE
1103A FLOATING POINT INSTRUCTIONS

Date: 15 October 1956

Prepared by: P. Warburton

Issued by: Systems Analysis Dept.
Systems Group of Univac Scientific Applications

October 12, 1956

The layout of the "Floating Point Content of Registers" is not the same as that of the fixed point instructions. There are more conditions affecting the final content of A. First, has the NEFF been set or cleared by instruction 05? Second, what is the relative size of (u) and (v)? For these reasons, only the Pack and Unpack commands are in the usual format. Since the arithmetic Floating Point commands do not change (u) and (v), $(u)_f$ and $(v)_f$ are not included in the Contents of Registers of operations 64, 65, 66, 67, 01, and 02.

The binary point of floating point numbers is usually between the twenty-eighth and the twenty-seventh place. After the arithmetic pseudo-normalizing process, the mantissa is in A_{11} , and the binary point is between A_{63} and A_{62} . It may or may not be normalized. The position of the most significant bit (MSB) indicates what has occurred. If normalized, the MSB will be in A_{62} .

The value of the significant bits depends upon whether rounding has occurred. Rounding in effect adds an extra bit to the value of (a) at A_{35} (unless the addition of the rounding bit carries into A_{62} , in which case the final left shift is omitted and the rounding bit remains added to the value of A_{34}).

The value of $(Q)_f$ will be either (1) the normalized rounded, and packed result (NRP), or (2) the pseudo-normalized result (PN).

NOTE: If A or Q is the v-address of any floating point command other than the pack or unpack command (A) or (Q) will be destroyed by the Unpack (u) sequence before the unpack (v) sequence is reached.

Instruction: Floating Add (FAuv)

Operation:

64

Function: Form in Q the normalized rounded and packed floating point sum of (u) and (v).

| NE FF | Arithmetic Conditions | | $(A)_f$ | | | $(Q)_f$ | |
|----------|--------------------------|------------------------|--------------|---|-------|---------|-------------|
| | | | MSB | Value of significant bits | Round | Norm | Value |
| 0 | $(u) \geq (v)$ | | A_{62} | $(u_m) \cdot 2^{(u_c)} - (v_c) + (v_m)$ | yes | NRP | $(u) + (v)$ |
| | $(u) < (v)$ | | A_{62} | $(v_m) \cdot 2^{(v_c)} - (u_c) + (u_m)$ | yes | NRP | $(u) + (v)$ |
| 1 | $(u) \geq (v)$ | $(u_c) - (v_c) \geq 2$ | A_{61} | $(u_m) \cdot 2^{(u_c)} - (v_c) + (v_m)$ | no | PN | $(u) + (v)$ |
| | | $(u_c) - (v_c) < 2$ | A_{61-A33} | $(u_m) \cdot 2^{(u_c)} - (v_c) + (v_m)$ | no | PN | $(u) + (v)$ |
| | $(u) < (v)$ | $(v_c) - (u_c) \geq 2$ | A_{61} | $(v_m) \cdot 2^{(v_c)} - (u_c) + (u_m)$ | no | PN | $(u) + (v)$ |
| | | $(v_c) - (u_c) < 2$ | A_{61-A33} | $(v_m) \cdot 2^{(v_c)} - (u_c) + (u_m)$ | no | PN | $(u) + (v)$ |

Instruction: Floating Subtract (FSuv)

Operation:

65

Function: Form in Q the normalized, rounded and packed floating point difference of (u) and (v).

| NE FF | Arithmetic Conditions | | $(A)_f$ | | | $(Q)_f$ | |
|----------|--------------------------|------------------------|-------------------|---|-------|---------|-------------|
| | | | MSB | Value of significant bits | Round | Norm | Value |
| 0 | $(u) \geq (v)$ | | A_{62} | $(u_m) \cdot 2^{(u_c)} - (v_c) - (v_m)$ | yes | NRP | $(u) - (v)$ |
| | $(u) < (v)$ | | A_{62} | $(v_m) \cdot 2^{(v_c)} - (u_c) - (u_m)$ | yes | NRP | $(u) - (v)$ |
| 1 | $(u) \geq (v)$ | $(u_c) - (v_c) \geq 2$ | A_{61} | $(u_m) \cdot 2^{(u_c)} - (v_c) - (v_m)$ | no | PN | $(u) - (v)$ |
| | | $(u_c) - (v_c) < 2$ | $A_{61} - A_{33}$ | $(u_m) \cdot 2^{(u_c)} - (v_c) - (v_m)$ | no | PN | $(u) - (v)$ |
| | $(u) < (v)$ | $(v_c) - (u_c) \geq 2$ | A_{61} | $(v_m) \cdot 2^{(v_c)} - (u_c) - (u_m)$ | no | PN | $(u) - (v)$ |
| | | $(v_c) - (u_c) < 2$ | $A_{61} - A_{33}$ | $(v_m) \cdot 2^{(v_c)} - (u_c) - (u_m)$ | no | PN | $(u) - (v)$ |

Instruction: Floating Point Multiply (MPuv)

Operation: 66

Function: Form in Q the normalized rounded and packed floating point product of (u) and (v).

| NE | Arithmetic | $(A)_f$ | | | $(Q)_f$ | |
|----|--------------------------------------|-----------------|---------------------------|-------|---------|-----------------|
| | | MSB | Value of significant bits | Round | Norm | Value |
| 0 | | A ₆₂ | $(u_m) \cdot (v_m)$ | yes | NRP | $(u) \cdot (v)$ |
| 1 | $(u_m) \cdot (v_m) \geq \frac{1}{2}$ | A ₆₁ | $(u_m) \cdot (v_m)$ | no | PN | $(u) \cdot (v)$ |
| | $(u_m) \cdot (v_m) < \frac{1}{2}$ | A ₆₀ | $(u_m) \cdot (v_m)$ | no | PN | $(u) \cdot (v)$ |

Instruction: Floating Point Divide (FDuv)

Operation: 67

Function: Form in Q the normalized, rounded and packed floating point quotient of $(u) \div (v)$

| NE | Arithmetic | $(A)_f$ | | | $(Q)_f$ | |
|----|---------------------------|----------|---------------------------|-------|---------|----------------|
| | | MSB | Value of significant bits | Round | Norm | Value |
| 0 | | A_{62} | $(u_m) \div (v_m)$ | yes | NRP | $(u) \div (v)$ |
| 1 | $(u_m) \div (v_m) \geq 1$ | A_{61} | $(u_m) \div (v_m)$ | no | PN | $(u) \div (v)$ |
| | $(u_m) \div (v_m) < 1$ | A_{60} | $(u_m) \div (v_m)$ | no | PN | $(u) \div (v)$ |

Instruction: Floating Point Polynomial Multiply (FPuv)

Operation: 01

Function: Form in Q the sum of (v) and the product of $(Q)_i \cdot (u)$

(NE FF should be cleared for the execution of this instruction. If it is not the product mantissa will be rounded not with one, but with (A_L) .)

| NE FF | Arithmetic Condition | $(A)_f$ | | | $(Q)_f$ | |
|----------|-------------------------|----------|---|-------|---------|------------------|
| | | MSB | Value of mantissa | Round | Norm | Value |
| 0 | $(Q)(u) \geq (v)$ | A_{62} | $(Qu)_m \cdot 2^{(Qu)_c - (v_c) + (v_m)}$ | yes | NRP | $(Q)_i(u) + (v)$ |
| | $(Q)(u) < (v)$ | A_{62} | $(v_m) \cdot 2^{(v_c) - (Qu)_c + (Qu)_m}$ | yes | | |

Instruction: Floating Point Inner Product (Fluv)

Operation: 02

Function: Form in Q the normalized, rounded and packed sum of (Q_i) and the product of (u) and (v) .

(NE FF should be cleared for the execution of this instruction; if it is not, the product mantissa will be rounded, not with one, but with (A_L) .)

| NE FF | Arithmetic Condition | $(A)_f$ | | | $(Q)_f$ |
|----------|-------------------------|----------|---|-------|----------------------|
| | | MSB | Value of significant bits | Round | Norm Value |
| 0 | $(Q)_i \geq (u)(v)$ | A_{62} | $(Q_m)_i \cdot 2^{(Q_c)_i - (uv)_c + (uv)_m}$ | yes | NRP $(Q)_i + (u)(v)$ |
| | $(Q) < (u)(v)$ | A_{62} | $(uv)_m \cdot 2^{(uv)_c - (Q_c)_i + (Q_m)_i}$ | yes | NRP $(Q)_i + (u)(v)$ |

Instruction: Floating Point Unpack (UP_{uv})

Operation: 03

Function: Unpack (u) replacing (u) with (u_m) and replacing (v_c) with (u_c) or its complement if (u) is negative. The characteristic portion of (u)_f contains sign bits. The sign and mantissa bits of (v)_f are cleared to zero.

| Storage Class | | Contents of Register & Storage Position After Operation | | | | | |
|----------------|----------|---|-------------------|-----------------|--------------------------------|------------------|--------------------------------|
| | | (MC) _f or (MD) _f | (A) _f | | | (Q) _f | |
| u | v | u | v | MSB | Value of bits | Round | |
| MC or MD | MD or MC | (u _m) | (u _c) | | No change | | No change |
| | A | (u _m) | — | A ₃₄ | (u _c) | no | No change |
| | Q | (u _m) | — | | No change | | (u _c) |
| A | MD or MC | — | (u _c) | A ₂₆ | (A _m) ₁ | no | No change |
| | A | — | — | A ₃₄ | (A _c) ₁ | no | No change |
| | Q | — | — | A ₂₆ | (A _m) ₁ | no | (A _c) ₁ |
| Q | MD or MC | — | (u _c) | | No change | | (Q _m) ₁ |
| | A | — | — | A ₃₄ | (Q _c) ₁ | no | (Q _m) ₁ |
| | Q | — | — | | No change | | (Q _c) ₁ |

Instruction: Normalize, Round, & Pack (NPrv)

Operation: 04

Function: Replace (u) with the normalized rounded packed floating point number obtained from the possibly unnormalized mantissa in $(u)_i$ and the biased characteristic in $(v)_c$.

It is assumed that $(u)_i$ has the binary point between u_{27} and u_{26} ($(u)_i$ is scaled 2^{-27}).

| Storage Class | | Contents of Registers & Storage Position After Operation | | | | | |
|----------------|----------|--|-----------|----------|---------------------------|-------|-------------------------|
| | | $(MC)_c$ or $(MD)_f$ | | $(A)_f$ | | | $(Q)_f$ |
| u | v | u | v | MSB | Value of bits | Round | |
| MC or MD | MD or MC | $NRP(u) + (v)_c$ | No change | A_{62} | $(u_m)_f$ | yes | No change |
| | A | $NRP(u) + (v)_c$ | --- | A_{62} | $(u_m)_f$ | yes | No change |
| | Q | $NRP(u) + (v)_c$ | --- | A_{62} | $(u_m)_f$ | yes | No change |
| A | MC | --- | No change | A_{34} | $NRP(A_R)_i + (v)_c$ | yes | No change |
| | MC | --- | No change | A_{34} | $NRP(A_R)_i + (v)_c$ | yes | No change |
| | A | --- | --- | A_{34} | $NRP(A_R)_i + (A_{Rc})_i$ | yes | No change |
| | Q | --- | --- | A_{34} | $NRP(A_R)_i + (Q_c)$ | yes | No change |
| Q | MD or MC | --- | No change | A_{62} | $(u_m)_f$ | yes | $NRP(Q)_i + (v)_c$ |
| | A | --- | --- | A_{62} | $(u_m)_f$ | yes | $NRP(Q)_i + (A_{Rc})_i$ |
| | Q | --- | --- | A_{62} | $(u_m)_f$ | yes | $NRP(Q)_i + (Q_c)_i$ |

Instruction: Floating Point Normalize Exit (NEj)

Operation: 05

Function: If J=0 clear the normalize exit flip-flop (designated NFF); if j=1 set NFF to 1

- (a) The results of setting NFF to 1 is set forth in the "Contents of Registers"
- (b) When NFF is set to 1, it will remain set until cleared by another NEj - instruction
- (c) NFF must be cleared for FP, FI, and NF instructions

PRELIMINARY INFORMATION
ON THE
EXECUTION TIME OF THE
1103A FLOATING POINT INSTRUCTIONS

Date: 15 October 1956

Prepared by: F. Warburton

Issued by: Systems Analysis Dept.
Systems Group of Univac Scientific Applications

SUMMARY OF EXECUTION TIMES

| | | Max. | Min. |
|------------------------------|-----------------------|----------------|----------------|
| Floating add and subtract | $(N \leq 1)$ | 300 μ sec. | 144 μ sec. |
| | $(N) = (u_c) - (v_c)$ | | |
| | $(N \geq 2)$ | 236 | 148 |
| Floating multiply | | 380 | 162 |
| Floating divide | | 654 | 648 |
| Floating polynomial multiply | | 619 | 262 |
| Floating inner product | | 637 | 280 |
| Floating unpack | | 52 | 54 |
| Floating normalize pack | | 180 | 144 |
| Normalize exit | | 20 | 20 |

All times given include magnetic core reference time. If (u) is A, subtract 6 μ sec.; if Q, subtract 4 μ sec. All cases are for NE FF set to zero. If NE FF = 1, set K = 0 and subtract 12 μ sec. All cases include rounding. If the full number of normalizing shifts are made (35 for addition and subtraction, 2 for multiplication and division), the mantissa is zero and rounding is omitted. For this case, subtract 14 μ sec.

The following symbols are used in the formulas.

$N = (u_c) - (v_c)$ for operations 64, 65, 66, and 67

$N = (Qu)_c - (v_c)$ for operation 01

$N = (uv)_c - (Q_c)$ for operation 02

N_9 is the sign of this difference (corresponding to S_9 at the

points when $(S) = (u_c) - (v_c)$

or $(S) = (Qu)_c - (v_c)$

or $(S) = (uv)_c - (Q_c)$

K is the number of normalizing shifts (the number of shifts necessary to put the MSB of the arithmetic result of (u_m) and (v_m) in A_{61} -- maximum of 35 for addition and subtraction, 2 for multiplication and division).

Floating point add and subtract (FAuv and FSuv)

| | |
|----------------------------|--|
| MP 0 (Unpack (u) sequence) | 7 + 2(u ₃₅) |
| 1 (Unpack (v) sequence) | 7 + 2(v ₃₅) |
| 2 (Initial alignment) | 1 + 3(N ₉) |
| 3 (Final alignment) | 4 + 2(N ₉) + 2 N |
| 5 (NRP sequence) | 12 + (34 - N) + 2K |
| 6 & 7 (Set up NI) | 7 |
| <hr/> | |
| Total (in clock pulses) | 38 + 2(u ₃₅) + 2(v ₃₅) + 5(N ₉) + 2 N + (34 - N) + 2K |
| Total (in μsec.) | 76 + 4(u ₃₅) + 4(v ₃₅) + 10(N ₉) + 4 N + (68 - 2 N) + 4K |

Case I
N=0

Case II
N=1

| | | | |
|------------|------------|------------|------------|
| Max. | Min. | Max. | Min. |
| 76 | 76 | 76 | 76 |
| 4 | 0 | 4 | 0 |
| 4 | 0 | 4 | 0 |
| 10 | 0 | 10 | 0 |
| 0 | 0 | 4 | 4 |
| 68 | 68 | 66 | 66 |
| <u>136</u> | <u>0</u> | <u>136</u> | <u>0</u> |
| 298 μ sec. | 144 μ sec. | 300 μ sec. | 146 μ sec. |

Case III
N=2

Case IV
N=34

| | | | |
|------------|------------|------------|------------|
| Max. | Min. | Max. | Min. |
| 76 | 76 | 76 | 76 |
| 4 | 0 | 4 | 0 |
| 4 | 0 | 4 | 0 |
| 10 | 0 | 10 | 0 |
| 8 | 8 | 136 | 136 |
| 64 | 64 | 0 | 0 |
| <u>0</u> | <u>0</u> | <u>0</u> | <u>0</u> |
| 166 μ sec. | 148 μ sec. | 230 μ sec. | 212 μ sec. |

N ≤ 1, Maximum time: 300 μ sec.
Minimum time: 144 μ sec.

N ≥ 2, Maximum time: 236 μ sec.
Minimum time: 148 μ sec.

Note: In cases I and II, maximum addition times are 4 μ sec. less than shown. (If (u) and (v) are both positive, K = 0.)

Floating point multiply (FMuv)

| | |
|------------------------------|---|
| MP 0 (Unpack (u) sequence) | 7 + (u ₃₅) |
| 1 (Unpack (v) sequence) | 7 |
| *2 (Multiply sequence) | 40 + $\sum_{i=1}^{26} (u_{35} \oplus u_i) + 2(u_{35} \oplus u_0)$ |
| 5 (NRP sequence) | 20 + 2k |
| 6 & 7 (Set up NI) | 7 |
| Total (clock pulses) | $81 + (u_{35}) + 4 \sum_{i=1}^{26} (u_{35} \oplus u_i) + 2(u_{35} \oplus u_0) + 2k$ |
| Total (μ sec.) | $162 + 2(u_{35}) + 8 \sum_{i=1}^{26} (u_{35} \oplus u_i) + 4(u_{35} \oplus u_0) + 4k$ |
| Maximum time: 380 μ sec. | |
| Minimum time: 162 μ sec. | |

*If (u) is negative, the complement of (u) is sent to Q. Therefore, Q₃₅₋₂₇ is always zero, and (Q₂₆₋₀) may be the complement of (u₂₆₋₀).

Floating point divide (FDuv)

| | |
|------------------------------|--------------------------------|
| MP 0 (Unpack (u) sequence) | 7 + (u ₃₅) |
| 1 (Unpack (v) sequence) | 7 |
| 2 (Initial shift of (u) | 36 |
| 3 (Divide sequence) | 222 |
| 4 (Q → A sequence) | 6 |
| 5 (NRP sequence) | 39 + 2k |
| 6 & 7 (Set up NI) | 7 |
| Total (clock pulses) | 324 + (u ₃₅) + 2k |
| Total (μ sec.) | 648 + 2(u ₃₅) + 4k |
| Maximum time: 654 μ sec. | |
| Minimum time: 648 μ sec. | |

Floating point polynomial multiply (FPuv)

| | | |
|----------------|--------------------------|---|
| MP 0 | (Unpack (Q) sequence) | 5 + (Q ₃₅) |
| 1 | (Unpack (u) sequence) | 7 |
| 2 | (Multiply sequence) | 40 + 4 $\sum_{i=1}^{26} (Q_{35} \oplus u_i) + 2(Q_{35} \oplus u_0)$ |
| (3) | (NRP (Q) · (u) sequence) | 14 |
| (4) | (Unpack (v) sequence) | 7 + (v ₃₅) |
| 3 ¹ | (Initial alignment) | 1 + 3(N ₉) |
| 4 ¹ | (Final alignment) | 4 + 2(N ₉) + 2 N |
| 5 | (NPP sequence) | 12 + (34 - N) + 2K |
| 6&7 | (Set up NI) | 7 |

$$\text{Total (clock pulses): } 97 + (Q_{35}) + 4 \sum_{i=1}^{26} (Q_{35} \oplus u_i) + 2(Q_{35} \oplus u_0) + 5(N_9) + 2|N| + (34 - |N|) + 2K$$

$$\text{Total (}\mu\text{ sec.): } 194 + 2(Q_{35}) + 8 \sum_{i=1}^{26} (Q_{35} \oplus u_i) + 4(Q_{35} \oplus u_0) + 5(N_9) + 4|N| + (68 - 2|N|) + 4K$$

Maximum and minimum times depend upon the value of N as well as (Q).

(See the four cases given under Floating add and subtract.)

Taking the largest maximum (N=1) and the smallest minimum (N=0), the maximum and minimum time are:

Maximum time (N = 1): 619 μ sec.

Minimum time (N = 0): 262 μ sec.

Floating point inner product (Fluv)

| | | |
|----------------|-------------------------------------|--|
| MP 0 | (Q → F ₄ sequence) | 7 |
| 1 | (Unpack (u) sequence) | 7 + (u ₃₅) |
| (2) | (Unpack (v) sequence) | 7 |
| (3) | (Multiply sequence) | 40 + 4 ∑ _{i=1} ²⁶ (u ₃₅ ⊕ u _i) + 2(u ₃₅ ⊕ u ₀) |
| (4) | (NRP (u) · (v) sequence) | 14 |
| 2 ¹ | (Unpack (F ₄) sequence) | 7 |
| 3 ¹ | (Initial alignment) | 1 + 3(N ₉) |
| 4 ¹ | (Final alignment) | 4 + 2(N ₉) + 2 N |
| 5 | (NRP sequence) | 12 + (34 - N) + 2K |
| 6&7 | | 7 |

Total (clock pulses): 106 + (u₃₅) + 4 ∑_{i=1}²⁶ (u₃₅ ⊕ u_i) + 2(u₃₅ ⊕ u₀) + 5(N₉) + 2|N| + (34 - |N|) + 2K

Total (μ sec.): 212 + 2(u₃₅) + 8 ∑_{i=1}²⁶ (u₃₅ ⊕ u_i) + 4(u₃₅ ⊕ u₀) + 10(N₉) + 4|N| + (68 - 2|N|) + 4K

Maximum and minimum times depend upon the value of N as well as (u).

(See the four cases given under Floating add and subtract.)

Taking the largest maximum (N = 1) and the smallest minimum (N = 0), maximum and minimum times are:

Maximum (N = 1): 637 μ sec.

Minimum (N = 0): 280 μ sec.

Floating point unpack (UPuv)

| | | |
|---------------------|-------------------------------|--------------------------|
| MP 0 | (Unpack (u) sequence) | 7 + (u ₃₅) |
| 1 | (u _m → m sequence) | 5 |
| 2 | (u _c → s sequence) | 1 |

| 6&7 | | <u>8</u> |
| Total (clock pulses) | | 72 + 2K |
| Total (μ sec.) | | 144 + 4K (9 > K ≥ 0) |

Maximum time: 180 μ sec.

Minimum time: 144 μ sec.

Floating point normalize exit (NEj=)

| | | |
|----------------------|------------|----------|
| MP 0 | (Clear x) | 1 |
| 1 | (Set NE FF | 1 |
| 5 | ----- | 1 |
| 6&7 | | <u>7</u> |
| Total (clock pulses) | | 10 |
| Total (μ sec.) | | 20 |

SUBJECT: Revision of the Card Package Routine (RR)

By the following modifications the Card Package Routine (CV37), which was written for the 1103, has been made useable on the 1103A.

A and Q Addresses

Accumulator and Q-register addresses have been modified to the standard address of each for the 1103A as follows:

A - From 20000 to 32000
Q - From 10000 to 31000

IOB Master Selection Bit

The IOB Master Selection Bit for the Card Unit has been changed from IOB6 for the 1103 to IOB35 for the 1103A. This change has been accomplished by modification of the instruction in which the Master Bit is introduced. This modification for the Card Read Routine and the Card Punch Routine now reads:

Read Routine - 72163 00161 01013 31 01211 00036
Punch Routine- 72361 00357 01007 31 01163 00036

Check Sum

A revision of the check sum for the transfer of the Card Package Routine to the ^{core}card has been made because of the above mentioned revisions throughout the routine. Thus the contents of the drum address 72313 now reads:

72313 00311 01143 23 72111 72133

CV-37

CARD PACKAGE IC 001

The Card Package Routine punches out on biocatal tape either of the card routines described below. The card routine punched out is modified according to a specified ES operating address (address of the first word of the card routine as it is stored for use in ES). In addition, the biocatal tape is punched with a specified insert address (storage address) which may or may not be the same as the ES operating address.

The Card Package sums itself after transfer to ES. If an improper sum is obtained, "SUM" is typed out by the supervisory typewriter and the 1103 stops. The routine tests the control word-- if it is not suitable, a new control word is asked for by typing out "set q".

OPERATING INSTRUCTIONS

- 1) Put 1103 in test mode.
- 2) Set PAK = 72000 and start.
- 3) a. If "SUM" types out, reread tape and rerun.
b. If "set q" types out, set up control word in (Q).
- 4) Control word.

(Q) = XO MMMMM mmmmm

X = 1 for card read routine.

X = 2 for card punch routine.

M = desired insert address.

00000 ≤ M ≤ 01777

40000 ≤ M ≤ 77777

m = desired ES operating address.

00000 ≤ m ≤ 01541

- 5) Turn on paper tape punch and start.

If X ≠ 1 or 2, or if M or m is not in the proper range, the routine asks for a corrected control word.

Either card routine requires 239 octal words of ES in which to operate, constants and temporary storage included.

The Card Package does not use the constant pool. ES is used and not restored.

Drum address: 72000 - 72531

CV-17
CARD READ ROUTINE

This subroutine causes the Bull Reproducer to go through a read cycle. The decimal information from the Bull Reproducer is converted to binary and scaled according to a given scaling factor. The results are then stored in specified ES memory locations.

CARD PUNCH ROUTINE

This subroutine converts specified binary numbers into decimal and sends equivalent coded-decimal information to the Bull Reproducer and causes it to go through a punch cycle.

These card routines require the following information:

- 1) Binary scaling.
- 2) Decimal scaling.
- 3) Locations of fields on the card.
- 4) Zero suppression (punch only).

This information is supplied to the card routine in a standard form called a parameter word. One parameter word is required for each card field.

A field consists of a number of consecutive card columns. The last column of a field is reserved for the sign of the decimal number stored in that field. An 11-punch signifies a negative number, no punch (blank column) signifies a positive number. A combination 12, 3 and 8 punch in one column represents a decimal point.

Fields need not be adjacent-- there may be unused columns, punched or unpunched, between them-- nor need they be alike in size.

Either card routine is entered from line y as follows:

```

y ) 37 mmmmmmm mmmmmmm ( to card routine )
y+1 ) AB P P P P P D D D D D ( control word )
y+2 ) Next Instruction

```

m represents the beginning address (ES operating address) of the card routine to be used.

The control word is described below.

The 37 command records in m the address of the control word. The routine is then entered at m. After finishing its operation, the card routine exits to y+2, the line following the control word.

CONTROL WORD

The control word controls the operation of the card routines. Its composition is as follows:

AB PPPP DDDDD

A, the first octal digit, controls positioning of cards in the read and punch channels of the Bull Reproducer.

- A = 1 Pick a read card from the read hopper.
- A = 2 Pick a punch card from the punch hopper.

B, the second octal digit, controls the operation to be performed.

- B = 1 Read a card.
- B = 2 Punch a card.

P is the address of the first parameter word.

D is the address of the first data word.

P and D both must be ES addresses.

The table on page 5 lists the combinations of operations that may be performed by the card routines.

PARAMETER WORD

A parameter word consists of twelve octal digits divided into six groups of two each:

FF SS BB LL RR ZZ

- FF: Flag for final parameter word.
FF = 77 octal for final word.
FF = 00 otherwise.
- SS: Binary scaling factor. (number of bits to the right of the binary point)
- BB: Number of blank or unused columns to the left of the field.
- LL: Number of digit positions to the left of the decimal point.
- RR: Number of remaining columns in the field, exclusive of sign. (number of decimal digits to the right of the decimal point plus one for the decimal point)
RR = 00 indicates no decimal point and no decimal fraction.

ZZ: Flag for zero suppression.
 ZZ = 77 octal for zero suppression.
 ZZ = 00 for no zero suppression. These two digits are decoded by the punch routine only. Only zeros in the integer part are suppressed. A zero immediately preceding the decimal point is not suppressed.

Range of the parameters:

| decimal | octal |
|-----------------|-----------------|
| 00 ≤ SS ≤ 35 | 00 ≤ SS ≤ 43 |
| 00 ≤ BB ≤ 63 | 00 ≤ BB ≤ 77 |
| 00 ≤ LL ≤ 10 | 00 ≤ LL ≤ 12 |
| 00 ≤ RR ≤ 11 | 00 ≤ RR ≤ 13 |
| 01 ≤ LL+RR ≤ 11 | 01 ≤ LL+RR ≤ 13 |

The parameter words, one for each field, must be stored consecutively starting at some ES memory location P. There must be an equal number of consecutive words starting with some ES memory location D, reserved for storing the results of the read routine, or filled with data for the punch routine.

Punching takes place at the third card station in the punch channel, therefore two punch cards must be advanced before punching can take place. This can be done manually, or either card routine can be used to position the cards as follows:

```

37 mmmmmmm mmmmmmm ( to card routine )
20 00000 00000 ( pick punch card )
37 mmmmmmm mmmmmmm ( to card routine )
20 00000 00000 ( pick punch card )

```

Reading takes place at the second card station in the read channel-- one read card must be advanced before reading takes place. This also may be done manually, or may be done by either card routine:

```

37 mmmmmmm mmmmmmm ( to card routine )
10 00000 00000 ( pick read card )

```

The card just advanced will not feed further unless another order to pick a card is given-- both pick and read orders must be given to read this card.

It should be noted that once a card enters either the read or punch channel it continues to advance one card station each time the Bull Reproducer is cycled.

Numbers are rounded to the desired number of decimal digits before punching takes place. A divide check error stop results if an insufficient number of card columns is allowed for the integer portion of a field.

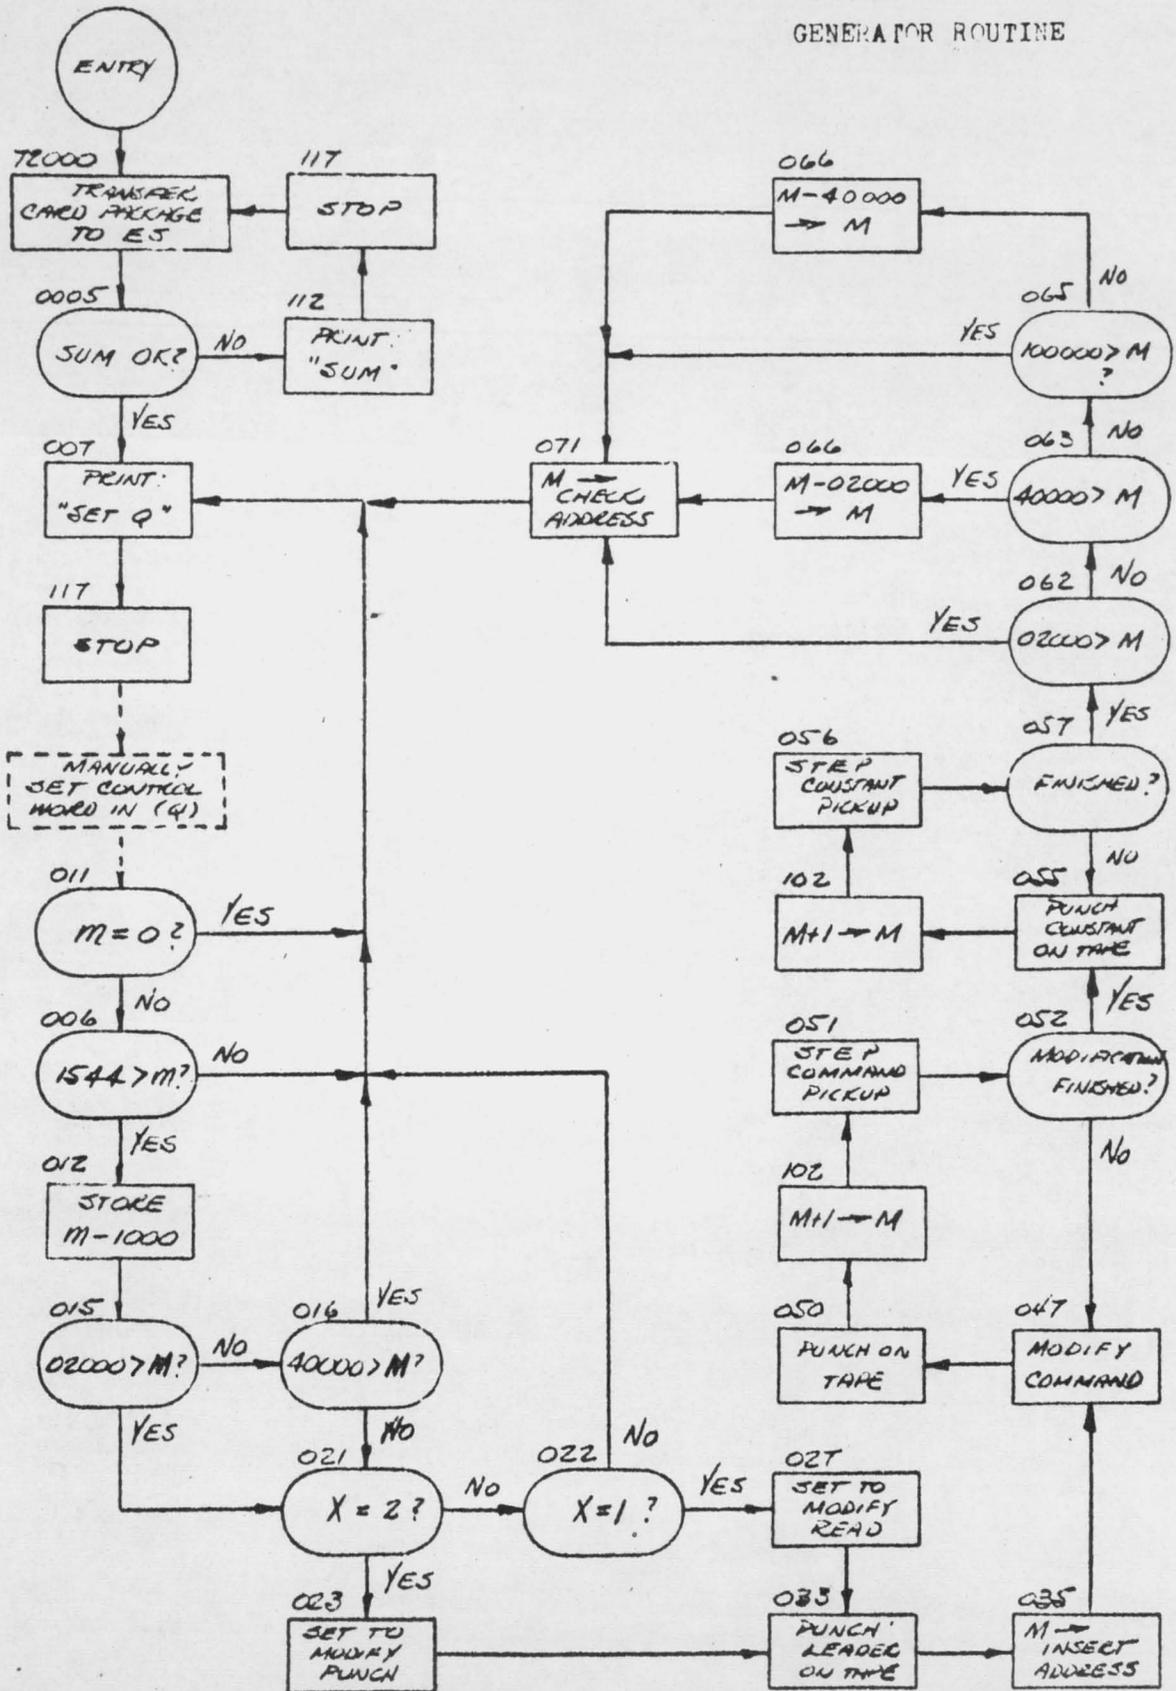

In case of a card machine failure or an accidental stop in the middle of a card cycle, the current card may be reread or punched again: reposition the cards, set PAK = 00000, and start.

CARD ROUTINE OPERATIONS

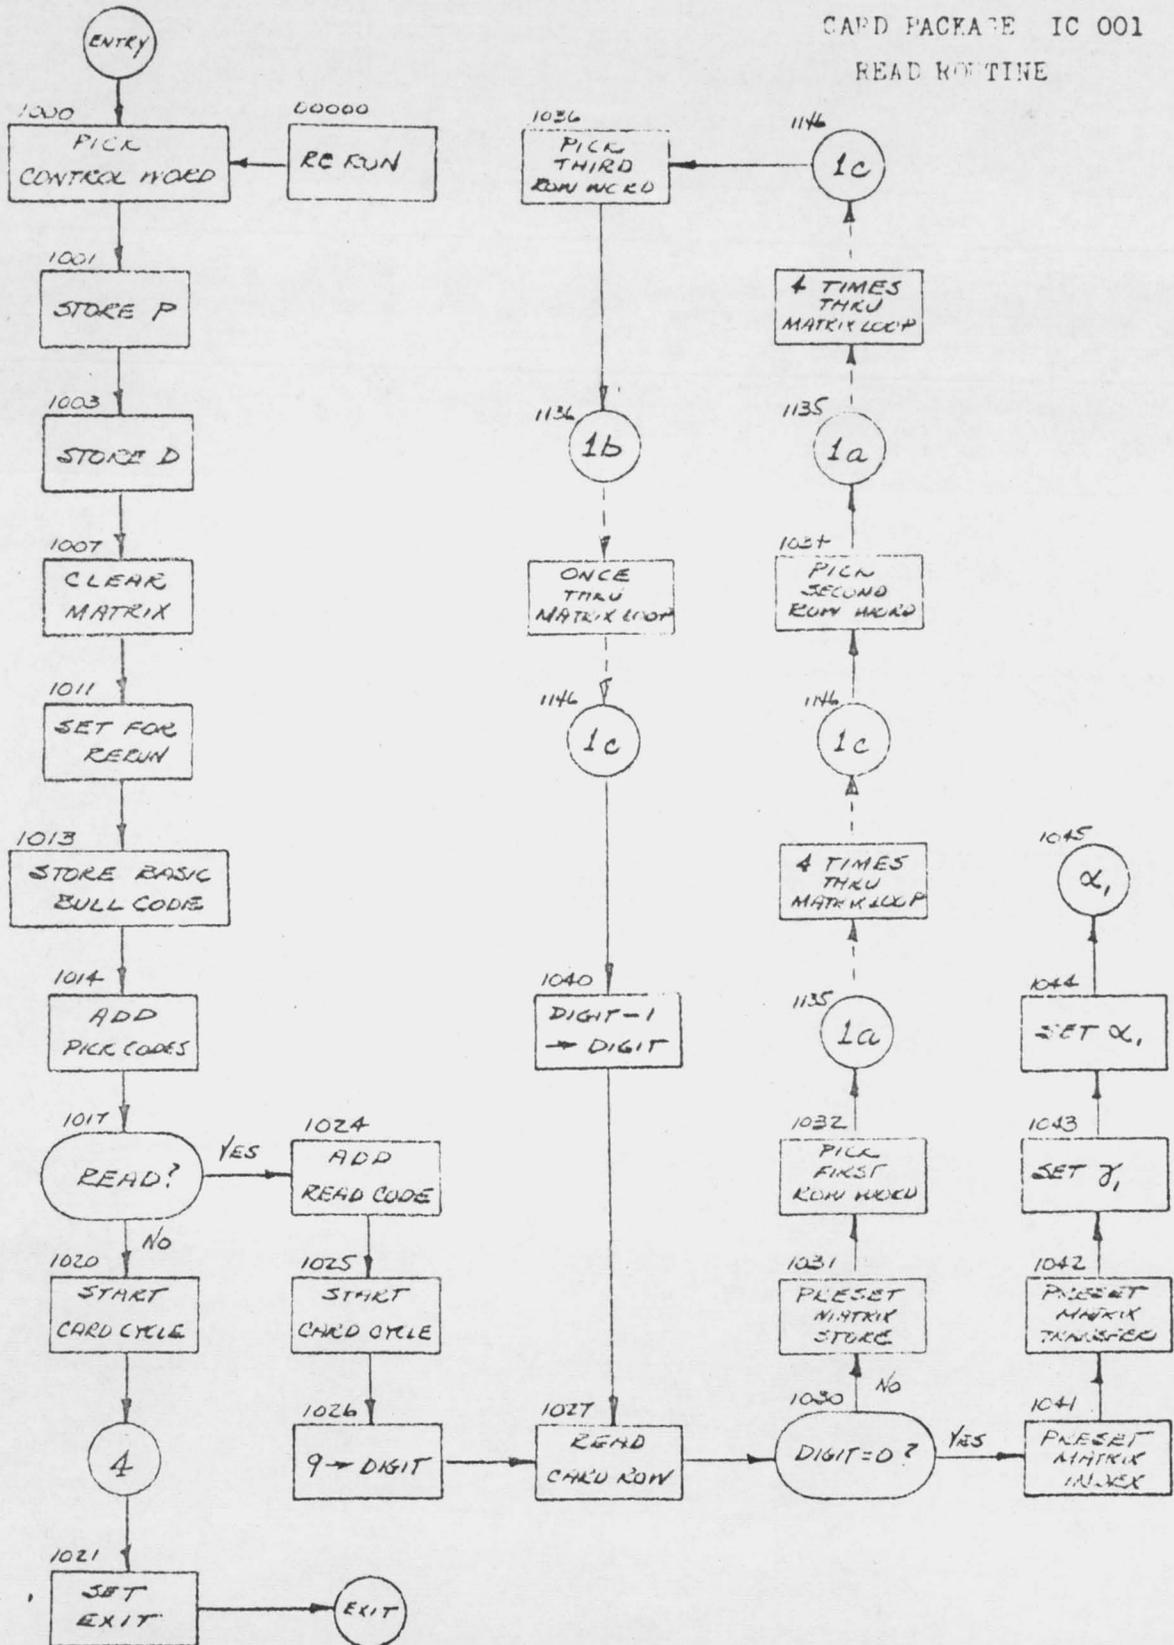

| A | B | OPERATION |
|---|---|--|
| 0 | 0 | Cycle Bull Reproducer. Cards already in either channel are advanced one card station. This operation also is performed with all of the following operations. |
| 0 | 2 | Punch a card. |
| 0 | 3 | Punch a card (when used with the punch routine-- do not use with the read routine). |
| 1 | 0 | Pick a card from the read hopper. This card is not in the read channel until the next card is picked from the read hopper. |
| 1 | 1 | Pick a card from the read hopper and read a card. |
| 1 | 2 | Pick a card from the read hopper and punch a card. |
| 1 | 3 | Pick a card from the read hopper and either read or punch a card. See note below. |
| 2 | 0 | Pick a card from the punch hopper. This card is not in the punch channel until the next card is picked from the punch hopper. |
| 2 | 2 | Pick a card from the punch hopper and punch a card. |
| 2 | 3 | Pick a card from the punch hopper and punch a card (when used with the punch routine-- do not use with the read routine). |
| 3 | 0 | Pick a card from both hoppers. |
| 3 | 1 | Pick a card from both hoppers and read a card. |
| 3 | 2 | Pick a card from both hoppers and punch a card. |
| 3 | 3 | Pick a card from both hoppers and either read or punch a card. See note below. |

Note: both routines can pick either or both read and punch cards. However, the read routine cannot be used to punch a card and the punch routine cannot be used to read a card. If both operations are called for, only one can take place.

USEful Note #5
SUBJECT: Double Precision Add, Multiply (RR)

Talmadge

HEADING

In order to complete the following routines as library subroutines in the USE format, the following heading should precede each routine. This heading will add 0.04 MS to each subroutine.

| Loc | op | u | v | Remarks |
|----------------|------|----------|-------|---------------|
| entry | MJ | 0 | start | entry line |
| error | RJ | diag + 2 | diag | error exit |
| exit | MJ | 0 | fill | normal exit |
| b ₁ | fill | 0 | 0 | } input data |
| b ₂ | fill | 0 | 0 | |
| c ₁ | fill | 0 | 0 | |
| c ₂ | fill | 0 | 0 | |
| d ₁ | fill | 0 | 0 | } output data |
| d ₂ | fill | 0 | 0 | |
| start | | | | } subroutine |
| . | | | | |
| . | | | | |

DOUBLE PRECISION ADD (METHOD 1)

Want $b + c = d$ $b = b_1 + b_2$ ditto c and d

Assume each word contains 35 bits preceded by a sign bit in one's complement form.

| Loc | op | u | v | Remarks |
|--------|-----|-------|-------|-----------------------|
| start | TP | b_1 | A | } add (0.24 MS) |
| | AT | c_1 | A | |
| | LA | A | 35 | |
| | AT | b_2 | A | |
| | AT | c_2 | A | |
| unpack | LTI | 0 | d_2 | } unpack (0.17 MS) |
| | LT | 1 | d_1 | |
| | TP | mask | Q | |
| | QS | d_1 | d_2 | |
| | MJ | 0 | exit | |
| mask | 40 | 0 | 0 | |

Total time = 0.41 MS

This routine ignores the fact that overflow may occur into bit 71 of the accumulator.

DOUBLE PRECISION ADD (METHOD 2)

Want $b + c = d$ $b = b_1 + b_2$ ditto c and d (one's complement form)

All words with subscript 2 contain 36 data bits and all words with subscript 1 contain 35 data bits preceded by a sign bit. Note: all numbers (b , c , and d) are in 1's complement form.

| Loc | op | u | v | Remarks |
|-------|-----|-------|-------|-----------------------|
| start | SP | b_1 | 0 | } add 0.20 MS |
| | SA | c_1 | 36 | |
| | SA | b_2 | 0 | |
| | SA | c_2 | 0 | |
| | LTL | 0 | d_2 | } unpack (0.08 MS) |
| | LT | 0 | d_1 | |
| | MJ | 0 | exit | |

Total time = 0.28 MS

This routine ignores the fact that overflow may occur into bit 72 of the accumulator. To test for overflow is not difficult nor lengthy but is omitted here. If the operations of multiply or divide are to be used also, this method of packing numbers for addition complicates these routines unduly and is not significantly faster for addition than method 1.

DOUBLE PRECISION MULTIPLY (METHOD 1)

Want $b \cdot c = d$ $d = b_1 \cdot c_1 + b_1 \cdot c_2 + b_2 \cdot c_1 + b_2 \cdot c_2$

Assume 35 bits and a sign bit in words with subscript 2 and 34 bits and two sign bits in words with subscript of 1 in one's compliment form. (Note: no change in method 1 add is necessary with these restrictions.)

| Loc | op | u | v | Remarks |
|--------|-----|-------|---------|----------|
| start | MP | b_2 | c_2 | } round |
| | LT | 1 | temp | |
| | MP | Q | c_1 | } mult. |
| | MA | b_1 | c_2 | |
| | AT | temp | A | |
| neg | SJ | neg | pos | } round |
| | SS | round | 0 | |
| pos | MJ | 0 | pos + 1 | } round |
| | SA | round | 0 | |
| unpack | LT | 1 | temp | } mult. |
| | MP | Q | c_1 | |
| | AT | temp | A | |
| | LTL | 0 | d_2 | |
| | LT | 1 | d_1 | } unpack |
| | TP | round | Q | |
| | QS | d_1 | d_2 | |
| round | MJ | - | exit | } 4 |
| | 40 | 0 | 0 | |

Max. error $\pm 1/2$ in the last place kept

average time of round = 0.39 MS

average time of multiply = 0.95 MS

average time of unpack = 0.17 MS

average total time = 1.52 MS

(Times, assume 0.27 MS for MP)

Note: this routine assumes only 69 places as input and output, (in general overflow occurs if more bits are assumed).

DOUBLE PRECISION MULTIPLY (METHOD 2)

Want $b \cdot c = d$

(See method 1 of multiply for scaling on b, c, and d)

$$d = b_1 \cdot c_1 + b_1 \cdot c_2 + b_2 + c_1$$

| Loc | op | u | v | Remarks |
|--------|------|-------|-------|--|
| start | MP | b_2 | c_1 | } Form $(b_2 \cdot c_1) + (b_1 \cdot c_2)$ scale down |
| | MA | b_1 | c_2 | |
| | LT | 1 | temp | |
| | MP | Q | c_1 | } Form d |
| AT | temp | A | | |
| unpack | | | | } See method 1 for unpacking routine |

Average time = **0.88** MS (assumes 0.27 MS for MP)

Average total time = **1.05** MS (including unpacking)

Max. error ± 1 in the last place kept

The main difference in these two methods of multiply is in the accuracy obtained. It should be noted that the maximum difference in the error between the two methods is only one place.

Further note that no overflow can occur as the result of **unpackings** (as in the add routines) in these two multiply routines.

USEful Note #6

Subject: Preliminary Information- General Tape Handler (RR)

PRELIMINARY INFORMATION--GENERAL TAPE HANDLER

The General Tape Handler is a routine to facilitate the use of the 1103A magnetic tape system. The routine provides built in checks which prevent the initiation of erroneous tape operations, and an error entry which makes use of information on the 'last' tape operation initiated correctly, to recover from faults occurring while tape is in operation. A parity check is made for each block read, and blocks in which errors occur are automatically re-read at different bias levels.

Initiation of tape operation

The tape handler is in the USE subroutine form with one parameter word which specifies the type of operation, etc. The parameter word is placed in location GTH+3, and routine is entered with a return jump.

Form of parameter word

R M T NN SS VVVV

R - octal digit which specifies operation

- 1 rewind
- 2 rewind/interlock
- 3 move forward
- 4 move backward
- 5 read forward
- 6 read backward
- 7 write

M - blockette spacing (for write only)

- M = 1 - 0" blockette spacing
- = 2 - 0.1" blockette spacing
- = 4 - 1.0" blockette spacing

T - block spacing and density (for write only)

- T = 0 1" block space 128 lines/in. density
- = 1 1" block space 50 lines/in. density
- = 2 2.4" block space 128 lines/in. density
- = 3 2.4" block space 50 lines/in. density

NN - number of blocks to be written (write only)

MTNN - number of blocks to be moved or read

SS - number of servo on which operation is to be performed

VVVV - High Speed Storage address for read and write

- 1) For write first word is taken from location specified by VVVVV. Succeeding words are taken from ascending storage locations.
- 2) For read forward first word is read into location specified by VVVVV and succeeding words are read into ascending storage locations.
- 3) For read backward first word is read into location VVVVV + 120n-1. (where n is number of blocks to be read) Succeeding words are read into descending storage locations, and the last word to be read is placed in VVVVV.

Sentinel blocks

The routine recognizes two types of sentinel blocks; lead and final. A complete block of all Σ words is recognized as a final sentinel. A block whose first and last blockettes are all Σ 's is recognized as a lead sentinel. The other four blockettes may also contain all Σ words, but at least one word must be a non - Σ word.

Errors detected by the routine

Upon detection of many errors, a code word is placed in a diagnostic routine (not a part of this routine), followed by a return jump to the diagnostic routine.

Errors which are treated this way are:

- (1) No operation specified ($R = 0$)
- (2) No blockette space designation
- (3) Read which would clobber the routine if executed
- (4) Read which would clobber F_1 to F_5 , or would try to read words into locations outside of high speed storage
- (5) Write, which takes words from locations outside of H.S.S.

If a parity error occurs, and attempts to reread the block at different bias levels are unsuccessful, the routine prints out p rf for read forward, or p rb for read backward and stops with PAK set to re-enter the reread routine.

If a final sentinel block is reached on a read or move forward n blocks before the nth block is read, tape is stopped, repositioned to first word of the sentinel block. The routine prints out s rf or s mf and stops with PAK set to exit from the routine. If the sentinel block is the nth block to be read, tape is repositioned to first word of block, but no print out is made and computer is not stopped.

If a lead sentinel is reached on a read or move backward n blocks before the nth block is read, tape is stopped, s rb or s mb is printed and computer stops with PAK set to exit from routine. Tape is not repositioned to last word of sentinel block, since the lead sentinel may contain information necessary to identify tape on next read forward.

If the lead sentinel block is the nth block tape is stopped but computer is not stopped.

Error entry

Most faults occurring while the tapes are in operation are recoverable by re-entering the routine from the error entry.

The one error which may not be recoverable is a >720 error in the last block to be read or moved. In this case computer coasts for ~ 80 m.s. before the fault stop. If < 6 extra lines are detected, a second tape operation cannot be initiated during this 80 m.s. coasting time since the instruction which would normally stop the tape has hung up in TCR without giving an IOB resume. If program is not altered during this coasting time, and other tape operations have not been started, recovery can be made by re-entering at error entry.

Indications of >720 error in last block

MT B fault indicator illuminated. Sprocket Error indicator in tape control cabinet illuminated. PCR contains something other than an ER. (If PCR contains an ER, the error was either a < 720 fault or a >720 fault in some block other than the last block to be read.) If less than six extra lines were detected TCR contains stop bits (6000). If more than six extra lines were detected the contents of TCR cannot be predicted, and another tape operation may have been initiated and a second fault may have been generated when the computer stopped.

NOTE: Copies of the GTH flow-charts are available upon request.

USEful Note, (ML1) Number 7

The following write-up contains a description of three non-standard 1103A routines to be used as preliminary acceptance tests.

1. NAME: ML TP1 Acceptance Test, Tape
Systems Development Group - 1 October 1956
Lockheed Missile Systems Division

METHOD: One hundred and twenty pseudo-random numbers are generated and stored in core. These numbers are then written onto tape, read back, and shifted circularly in sequence. The process is repeated 120 times and the resulting block is compared with an undisturbed image of the original block.

- OPERATION: 1. Set PAK to 00001.
2. Set low order of Q-register with Uniservo number if test is to be run using only one Uniservo.
3. Set M.J. switches.

| | 1 | 2 | 3 |
|-----|-----------------------|---------------|---|
| on | Test One Uniservo | Rewinds | - |
| off | Test All Uniservos | No Rewinds | - |

4. Set MS switches.

| | 1 | 2 | 3 |
|-----|------------------------|---|---|
| on | Stop and Continue | - | - |
| off | No Stop Repeat Test | - | - |

5. Depress Start

The following indications will appear on the typewriter:

OUTPUT: HUZAH - Test Successful

BADTPE - Program fails on any bias.

TAPE n NORMAL - Bias failure

TAPE n HIGH - Bias failure

TAPE n LOW - Bias failure

STOPS: (PAK) = 00001 Intermediate or final stop, depressing start button continues test with rewinding of Uniservos.

(PAK) = 00003 Intermediate or final stop, depressing start button continues test with no rewinding of Uniservos.

TIMING: Approximately three minutes for one test.

2. NAME: ML MD1, Magnetic Drum
Systems Development Group, 1 October 1956
Missile Systems Division

METHOD: Four thousand and ninety-six pseudo-random numbers are generated in two stops and stored as working storage on a logical drum. The same numbers are stored as a mirror image on another logical drum. The working storage is then rotated between drum and core 4,096 times with an offset of one. The final rotation is then compared against the mirror image. The program tests sequentially drum 5 working - drum 7 mirror, drum 6 working - drum 7 mirror, drum 7 working - drum 5 mirror, and finally drum 4 upper as working - drum 5 upper as mirror. It should be noted that the program is divided into four independent parts and thus a start may be initiated at any of the four divisions.

OPERATION: 1. Set F1 to 40001.
2. Set PAK to 40000, (40110, 40216, 40324, optional).
3. Depress Start Button.

STOPS; (PAK) = 40401 Final stop
(PAK) = 40454 Intermediate stop if error occurred while checking 2048 numbers.

OUTPUT: Typewriter is utilized for monitoring.
1. START w-m - Indicates which test is being executed by noting the working and mirror drums.
2. OK1 - Indicates first 2048 numbers check
3. OK2 - Indicates second 2048 numbers check.

ERROR ROUTINE: 1. Obtain as print out in octal of all errors occurring in checking 2048 random numbers using the following format:

| Location | Working Word | Mirror Word |
|----------|---------------|---------------|
| XXXXX | XXXXXXXXXXXXX | XXXXXXXXXXXXX |

2. Optional Start

a. Set high order position of Q-register to one for

repeat of test using same working and mirror storage
- Depress Start

b. Depressing Start continues test sequentially.

TIME: Approximately two hours for a complete test, 35 minutes each for the first three parts.

3. NAME: ML MD2, Leap Frog
Systems Development Group, 1 October 1956
Lockheed Missile Systems Division

PURPOSE: This program is intended to test the arithmetic circuits, memory retention, transfer of information from core to drum to core, and the interpretation circuits of the 1103A.

METHOD: The program prepares a copy of itself which is transmitted ahead to a new core location. During this process the arithmetic and interpretation circuits are checked. After transmission, the core to drum to core exchange is tested except when the program overlaps Fl.

OPERATION: 1. Set PAK to 46100.
2. Set MS switches.

| | 1 | 2 | 3 |
|-----|------------------|--------------|---|
| on | Stop, 4096 leaps | Stop, 1 leap | - |
| off | Continue | Continue | - |

3. Depress Start Button

STOPS: 1. Final Stop - Either a failure in the arithmetic section or a check sum failure from the core to drum to core transfer.
2. Intermediate Stop - Depends upon MS switch setting - depressing Start Button continues test.
3. Any Other Stop - Failure of core memory.

OUTPUT: None

TIMING: Approximately 80 minutes for 4096 leaps.

REMINGTON RAND UNIVAC

ST. PAUL DEPARTMENT--INFORMATION SCIENCE

18 December 1956
(Rev. 18 Feb. 1957)

1103 TO 1103A CONVERSION ROUTINE

- I. TYPE: Service routine or subroutine.
- II. STATUS: Code checked and machine checked by Bill Wallace.
- III. PURPOSE: This routine changes A and Q machine addresses from 20000 and 10000 to 32000 and 31000 respectively, and detects magnetic tape and external function instructions. Various options are provided for print out of those addresses where an A or Q reference is modified, (indicating also u or v portion) and punching the converted program in biocatal or flex code on paper tape.

IV. USAGE:

- A. STORAGE REQUIRED: The program is coded in RECO form and it is therefore possible to operate the program from a location providing 320 octal drum address and 2000 additional octal drum addresses for a HSS image region. Such a location of the program and image region is done by assigning the desired starting addresses to regions BB and IR respectively, of the reco tape (see coding) all other regions being in HSS, and hence remaining the same. The regional assignment can be on a separate tape from the main program reco tape, but this tape should have END. c.r. at the end. (See RECO write-up.)

In addition to the RECO tapes, a biocatal tape of the program is available where the program is stored at 66000-66320, with the image region 76000-77777.

- B. INPUT-OUTPUT: Output is a punched tape in biocatal or flex code of the changed program if desired. This option makes use of tape output routines which are not integral parts of this conversion routine. These output routines (Biocatal or Flex Dumps) are included in the Serial 9 1103 Service Library or may be found in the Minimum Service Routine Library for 1103A (See USEful Note #1). Also the following is printed out as the conversion routine is operating: (This is also optional.) u aaaaa or vaaaa, where aaaaa is the address where an A or Q reference has been modified and u or v shows whether the u or v address of the instruction has been modified. Also, TAPE is printed out when an 1103 magnetic tape instruction is encountered, and EF and address when an external function command occurs.
- C. OPERATING INSTRUCTIONS:
- (1) Used as a service routine proceed as follows: (the term "program" here refers to a program to be converted.)
 - a) Master clear, MD start
 - b) Set PAK to 66000, (or bb)

- c) Insert in Q_u the first address of the program
- d) Insert in Q_v the last address of the program
- e) Insert in v address of A_R the address of the last instruction of the program, or the last address of the program wherein one wishes to have A and Q addresses modified.
- f) Insert in v address of A_L the following codes for the various options:

00000 biocatal punch of converted program and print out of addresses where modification occurs.

00001 same as above but no print out.

00002 flex code punch of converted program and print out.

00003 same as above, but no print out.

00004 print out, but no punch of converted program.

00005 no print out and no punch of converted program.

A 56 0 66010 (bb10) stop occurs if a gross error is made in the set-up, e.g. transposition of Q_u and Q_v .

(2) Used as a subroutine, proceed as follows:

- a) Program the transfer of parameter as listed above to the A and Q registers.
- b) Execute the instruction:
RJ bb2 bb
- c) The options are selected in the same manner as previously shown.

(3)

- a) The use of this conversion routine assumes that the program to be converted is stored either all in core storage or all in drum storage.
- b) The conversion routine is coded for operation on either an 1103A, or on the 1103 (Serial 9) at RRU, St. Paul. If this conversion routine is to be used on an 1103A, provision must be made for the output routine mentioned in IV-B above.

RULES FOR SYMBOLIC CODING

For the KRA-1103 A Computer

For programs to be translated by

TRANS-USE-1

Prepared by

ROBERT G. TANTZEN

14 AUGUST 1956

Revised 11 December 1956

A. Introduction.

The 1103A computer works internally in the binary number system. Therefore, all information (numbers and instructions) must eventually have a binary machine representation. This is usually given in octal notation, which can be considered a shorthand writing of binary numbers. Writing programs in this absolute fashion is rather tedious work. Besides taking a long time, it is liable to coding and clerical errors. It is possible to let the computer do part of the tedious coding work. A step in this direction is the regional coding scheme. Another step forward is called symbolic coding, a system which has been adopted as the standard coding procedure by USE.

Symbolic coding replaces absolute numbers by names or symbols. As these names can be chosen to suggest certain ideas, a program in symbolic form is much more easily written and interpreted than the same program in absolute numbers. For example suppose we have to compute

$$y = (kx^2 + mx + n) \cdot \frac{1}{P}$$

Using suggestive symbols for addresses and mnemonic codes for the operations, the symbolic program would be:

```
START MP K TEMP
      AT M A
      MP A TEMP
      SA N 0
      DV P TEMP + 1
```

Trans-USE-1 will accept this symbolic code, assign correct numbers for the mnemonic commands, addresses for the other symbols, and thereby translate it into its absolute form which, e.g., could be:

```
00200 710030001000
00201 350033332000
```

00202 713200001000

00203 320033400000

00204 730035001001

The rules set up for using this symbolic coding to be translated by Trans-USE-1 are explained in detail in the rest of the paper.

B. Symbol

A symbol consists of from 1 to 6 characters, at least one of which must be alphabetic. The characters permitted are all letters A-Z and all numbers 0-9. The following symbols have special meanings and cannot be used in the location column.

1. The symbol "A" represents the octal number 32000 and refers to the accumulator.
2. The symbol "Q" represents the octal number 31000 and refers to the quotient register.
3. The symbol "D" represents the octal number 40000 and is used for references to the drum.
4. The symbol "FILL" in the operation or either address field indicates that that portion of the command is to be supplied by the program. In the u or v address fields, "FILL" will be replaced by the illegal address 30000. When used as an operation symbol, "FILL" will be replaced by 00.

C. Location

The location column of a line of coding may be blank or may consist of a single symbol. These symbols are used for reference purpose only and do not, in any way, determine the order in which the instructions finally appear in the memory. The sequence in which the instructions are written determines the order in which they are to be executed. The special symbols A, D, Q, and FILL may not be used as location symbols.

D. Operation

1. The two-character mnemonic abbreviations as prepared by Remington Rand are used for basic machine operation codes. Thus TP stands for 11, AT for 35, etc. In instructions requiring a "j" as part of the u-address the number "j" ($0 \leq j \leq 7$) is appended to the mnemonic operation abbreviation as a third character; so it will appear in the operation field rather than in the u-field. If $j = 0$, it may be omitted. To make coding easier, the number j may be replaced by a more suggestive character, e. g., ERB means ERL indicating a reading from LOB. The complete list of these operation symbols is stated below:

| | |
|-----------------|-----------------------------|
| LT = LTO = LTL, | LTL = LTR |
| PU = PUO = PU6, | PUL = PU7 (7 for 7th level) |
| ER = ERO = ERA | RP 1 = RPV |
| ERL = ERB | RP2 = RPU |
| EW = EWO = EWA | RP3 = RPB (B for both) |
| EWL = EWB | NE = NEO |

2. Trans-USE-1 will also accept 2 or 3 digit octal operation codes, whether or not these represent legal operations.

3. The operation symbols END, BREAK, RESERV, refer to pseudo-operations, see under G.

4. The operation symbols "B" and "X" are used to write absolute constants, see under F.

E. Addresses

1. Reference to a line of coding is made by putting in the u- or v-field the location symbol of that line to be referenced.

2. The programmer might wish to write an address not as a symbol but as an absolute number. Also, several instructions require a number in one of the addresses, e. g., SP u k or RP jnv. In these cases the coder will write a number in the address field. Trans-USE-1 will

consider numbers to be decimal, unless the letter B is attached at the end, in which case they are considered octal. For example, 16 is the decimal number 16 and 32000 B is the octal number 32000 or the address of the accumulator, normally written as "A".

3. In certain cases it is convenient to express an address as a combination of location symbols and numbers. It is legal to specify the sum or the difference of any two.

A few examples might be helpful. LOOP2 and LOOP3 are different symbols, their addresses are not related to each other. LOOP2 + 5 designates the 5th line of coding after LOOP2. LOOP2 - 3 is accordingly the 3rd line preceding LOOP2. LOOP2 - COMP will be translated into the difference of the absolute addresses assigned to the two symbols.

F. Constants.

Constants and numbers are always full words. Therefore, there is no separation of a word into operation, u- and v-fields. The machine internally considers all numbers to be integers. USE has established conventions for writing octal and decimal integers. On the coding sheet the letter "X" or "B" has to be written in the operation column to specify decimal or octal integers respectively. The u- and v-fields are considered as a unit, into which the desired number is entered. The number will be considered as a constant only if a B or X appears in the operation column. A sign may precede the digits. If omitted the constant is considered positive.

A few examples and their absolute octal equivalents follows:

| | |
|----------|-------|
| X | 100 |
| 00 00000 | 00114 |

| | |
|----------|-------|
| B | 100 |
| 00 00000 | 00100 |

X - 5
77 77771 77772

B 2 00001
00 00002 00001

Incidentally, the last constant could also be written by leaving the operation blank, write 2 in the u-field and 1 in the v-field. See under E2 and D2.

G. Pseudo-Instructions

These are instructions to the translation routine and do not form part of the translated program.

1. "BREAK" (BREAK --) Symbolic programs may be longer than 500 lines of coding, which is the capacity of one Unityper 200 ft. tape. Programs up to this size are typed on one single magnetic tape. Longer programs can be handled in segments of approximately 500 lines each. When reaching the end of a tape, the typist simply types a line of coding consisting of the word "BREAK" in the operation column, leaving all other columns blank (see example under L1). When encountering the BREAK operation, the computer will stop and wait for the next reel to be put on the same tape unit. Pushing the start button on the console will then cause the translation to continue. When reading from cards, BREAK may be used if desired.

2. "RESERV": (RESERV N N) This operation reserves, in memory, a block of N temporary cells. The symbol appearing in the location column will be assigned the current value of the address counter. This counter will then be incremented by the amount specified in the v-field. To make the program acceptable to the USE-compiler, both of the u and the v-field must contain the number of cells to be reserved. The coding lines containing a RESERV operation will occupy one cell each in the translated program. Therefore, they have to be at the end of a program directly preceding the "END" line. The end of a program will

then look something like this:

| <u>LOC</u> | <u>OP</u> | <u>u</u> | <u>v</u> | <u>remarks</u> |
|------------|-----------|----------|----------|------------------|
| C16 | 0 | 1 | 1 | address, modify |
| C17 | 0 | 24B | 0 | 20 in u |
| TEMP1 | | | | sin t |
| IMAGE | RESERV | 36 | 36 | card image |
| BLOCK | RESERV | 120 | 120 | tape information |

3. "END": (END---* The pseudo-instruction END is on the last line of coding. There must not be a symbol in the location column, the u- and v-fields are ignored. "END" signals the end of the program to be translated.

H. Coding Sheet.

The coding sheet is divided into 5 columns. The maximum permissible number of characters for each column is as follows:

| | |
|-----------|----|
| Location | 6 |
| Operation | 6 |
| u-address | 13 |
| v-address | 13 |
| Remarks | 18 |

I. General Rules of Coding

1. Any symbol may appear only once in the location column of a program. If it appears more often, the first (lowest) address will be assigned to that symbol.

2. References to subroutines and service routines are made by using an established symbol for each. If, for instance, a subroutine symbol is MATRIX, which could mean a matrix-multiply routine, the jump to the subroutine would be

RJ MATRIX + 2 MATRIX.

Where to supply operands and to acquire results may be found in a table of subroutines, which will be available at each installation.

See also USE-standards for subroutines.

3. The normal use of the repeat instruction (RP jn w) requires a jump command in cell 00000 (the w is placed in the v portion). The programmer should make sure that it is there.

4. Free symbols: Usually the programmer does not care what addresses are being assigned to symbols of temporaries. He then does not write them in a location column. These so-called free symbols will be assigned successive addresses at the end of the program in the order in which they appear on the coding sheet.

5. Symbols may consist of an arbitrary mixture of letters and numbers. Some characters therefore, may cause some uncertainty as to which one is meant. The character "0" may be the letter "O" or the number zero. To avoid confusion it is good policy to choose only symbols which imply an unambiguous meaning. A "0" standing alone is always a zero. Symbols like CO or PO3 should be avoided. A general rule to go by is that 0 is always a zero unless included between letters. In handwriting care should be taken to distinguish between 2 and Z, 1 and I, 5 and S.

6. If all or part of an instruction will be computed and supplied by the program, the symbol FILL should be written in the corresponding columns. This is a safety device. If the program does not provide the information for some reason or other, the computer will stop with an MCT or SCC fault indication. See also under B4.

7. Never assume any temporary cell to initially contain certain information. Sometimes the whole memory will be cleared before reading-in a program. Then the temporaries would be zero. However, it is safer not to take this for granted.

J. Arrangement of a Program

Programs to be translated and assembled consist of three sections

which must be written in the following order.

1. Section 1, n_1 words, containing all words subject to address modification, usually commands and relative constants.

2. Section 2, n_2 words, containing all absolute constants. This section also includes those temporaries which are assigned locations by placing their symbols in a location column.

3. Section 3, n_3 words, consisting of the number of temporaries used, not including those already accounted for in section 2.

The total memory space a program needs is $n_1 + n_2 + n_3$ cells. All information constituting a program is contained in sections 1 and 2. Therefore, the translation extends over $n_1 + n_2$ words only.

K. Parameters

For checking and control purposes each program must be preceded by 6 lines of coding containing the following parameters:

1. ITA: Initial translation address which shall be assigned by the translation to the first line of the body of the program.

2. n_1 : The number of words subject to address modification (see under J).

3. n_2 : The number of absolute constants and, possibly, certain temporaries (see under J).

4. n_3 : The number of temporary locations used (see under J).

5. p : Is used only in subroutines, and is the number of operands or control data needed by a subroutine.

6. r : Is used only in subroutines, and is the number of results yielded by a subroutine.

In programs other than subroutines the values of p and r are irrelevant, but they must not be omitted. In addition to the above 6 parameters, a 6 character identification tag for the program, the first 2 characters identifying the installation (for Holloman, HO),

must appear in the comments field of the first line of coding. The above mentioned parameters may be given as constants using either the B or X operation. So the first 6 lines of coding will look like this:

| <u>LOC</u> | <u>OP</u> | <u>u</u> | <u>v</u> | <u>Remarks</u> |
|------------|-----------|----------------|----------|----------------------|
| | B or X | ITA | | Identification |
| | B or X | n ₁ | | Title of Program |
| | B or X | n ₂ | | Title of Program |
| | B or X | n ₃ | | Other information, |
| | B or X | p | | as: date, coder, |
| | B or X | r | | project number, etc. |

L. Typing a symbolic program

For input to the computer a symbolic program must either be typed on magnetic tape with the Unityper, or key-punched on IBM cards.

1. Magnetic tape.

After inserting a reel of tape into the Unityper and loading the leader, the program is typed starting with the first line of coding (containing ITA). The fields are separated by commas, even if they contain no information. Spaces may be typed anywhere; they are ignored by the translation program except in the remarks column. After a line of coding has been typed the rest of the blockette is filled with zeros (tabulator key). An inter-blockette space is then generated with the trip key. Each coding line will thus occupy one line on the Unityper paper and correspondingly one blockette on tape.

To give an idea of how a program looks on paper, here are a few examples:

```

TRANS, TP, FILL, BT, COMMAND TO BT
MODIF, RA, TRANS, C18, MODIFY + 20
,TP, BT + 1, A, OPERATION TO A
,D, 31415926, F1 SCALED + 7
,BREAK,,,

```

Note that each line normally has 4 commas. Only for constants (B and X operation symbols) are there 3, because the u and v fields are considered as a unit.

A program might be too long for one reel of tape. Then the typist must type the BREAK instruction on the end of that tape before continuing on a new one. See under G1.

2. IBM - Cards.

The five fields of the coding sheet are assigned certain columns on the cards. The rest of the card is used for information generated by Trans-USE-1; in this way cards punched out by the translation program, containing both the symbolic and absolute program for side by side listing, may be reused for input. The field allocation is as follows:

| | | |
|--------------|---------|--|
| Card Columns | 1 - 6 | location |
| | 7 - 12 | operation |
| | 13 - 25 | u-address, constants |
| | 26 - 38 | v-address, |
| | 39 - 56 | remarks |
| | 57 - 60 | absolute octal address |
| | 61 - 72 | absolute octal word |
| | 73 - 75 | decimal sequence number |
| | 76 | insert digit |
| | 77 - 80 | identification tag, last 4 characters. |

Besides punching the information from the coding sheet, the key punch operator has to punch sequence numbers. These (positive) numbers must be in ascending order. This enables the translation routine to check on the correct sequence of the cards read. The sequence numbers on the first card may be any, including zero. The sequence check may be bypassed

by setting a switch on the console of the computer.

M. How to make Changes in a Program

1. Corrections: Replace the incorrect cards by correct ones.
2. Deletions: Simply take out the unwanted cards.
3. Insertions: New cards may be inserted any place in the program. They should contain the sequence number of the card after which they are inserted and also an insert digit, which will be regarded in the sequence test as a decimal fraction added to the integral sequence number.

After each change the program must be retranslated. Care should be taken to correct n_1 and n_2 when making changes.

N. Size limit of a program

Trans-USE-1 has been coded for the "minimum 1103-A", which contains 4096 words of core memory. There is, however, no fixed limit on the size of a symbolic program, as far as the translation goes. The only restriction is the number of different symbols, which cannot exceed 245. This number does not include the special fixed symbols and the subroutine symbols. For the assembly the size of a program is directly determined by the core capacity. The following two conditions must both be satisfied:

- 1) The assembled program must not go beyond address 07200. For a program without subroutines the last line of coding should not go beyond that point. If subroutines are used, the last word of the last subroutine must stay under this limit.
- 2) The temporary region used for execution of the program should not exceed core capacity (address 07777).

As the lowest initial assembly address IAA is 00014, a complete program can have up to 3700 words, and 4083 words including the temporaries. Larger programs can be handled, if they can be broken up into independent sections.

INDEX

| | | | |
|-------------------------|---------------|--|------------------|
| A | 2, 4 | location | 3, 6, 8 |
| address, absolute | 4, 8 | n ₁ n ₂ n ₃ p r | 11 |

OPERATING INSTRUCTIONS

FOR

TRANS-USE-1

AN 1103-A SERVICE ROUTINE

DATE: 1 Dec 56
Prepared by: Robert G. Tantzzen
Issued by: Holloman Air Development Center
Computers Division

A. Normal Operating Procedure.

1. Make sure Trans-Use-1 is loaded (on 60,000 drum).
2. Make sure the subroutine library is loaded (if the programs to be translated refer to same).
3. Put symbolic program tape on TU1 (tape unit logical) or put symbolic cards in reader, do not cycle Bull. Place blank cards in punch. Set Bull for 3 fields.
4. Put tapes on TU2, TU3, and TU4. TU3 and TU4 must be rewound.
5. If input from tape, turn MJ1 on.
6. Optional: If check on sequence numbers from input cards shall be bypassed, turn MJ2 on. (Applies for card input only).
7. If assembly is to be indirect, turn MJ3 on.
8. Set PAK=60,000 and start.

Stops: PAK=60,121 Alarm print. Look at typewriter print-out. Refer to list of alarm prints below and decide what to do.

PAK=60,002 Typewriter has printed a "t" indicating the end of current translation. If another translation is wanted, go back to 5. If assembly is wanted combine with 9.

PAK=04412 MJ1 on: Tape with symbolic program is used up, a "BREAK" is found. Put next symbolic tape on TU1 and start.

MJ1 off: A "BREAK" card is read. Put more input cards in reader, cycle Bull once and start.

REMARKS: Should Bull mispick a read card, start all over. Should Bull mispick a punch card, resume computation at 04660. All cards except the first 6 will be repunched. This procedure good only if less than 120 cards have been punched so far.

9. Recheck choice for direct or indirect assembly. If change is wanted, set MJ3 now, and reset PAK to 60002.
10. Direct run: Start
Indirect run: Put "Assembly Control Card" in reader, do not cycle Bull. Ascertain that TU4 is rewound, and start.

Stops: PAK=60121 Alarm print. Look at typewriter print-out. Refer to list of alarm prints below and decide what to do. Alarm print with tagword "assemb" Indicates successful end of assembly. To execute first assembled program, start. Programs 2, 3, 4, of this assembly can be started at 00011, 00012, 00013 respectively. If another assembly is wanted, combine with 11.

11. Put tape with translation(s) on TU3, another tape on TU4, then go to 9.

B. List of Alarm Prints.

Each alarm print consists of a 6-character tagword followed by the contents of A and Q. The computer stops with PAK=60121. To resume computation, start.

An explanation of the alarm prints follows, specified by the different tagwords printed.

"seq no" Occurs on card input only.

Fault: The last card read has a sequence number not larger than the previous one. A and Q hold the new and old sequence numbers in excess 3.

Remedy 1: If proper card sequence does not matter, start.

Remedy 2: Get deck of cards in proper order and go back to 3 and rewind TU3. If previous translations are already recorded on TU3, a new tape should be taken.

"parity" A=1. Occurs during translation only.

Fault: A parity error is found while reading TU2 or TU1.

Remedy: Determine from console which tape unit failed. Try another tape or another tape unit.

"length" Fault: The length of the program being translated does not agree with the sum of the parameters N_1 & N_2 .

A contains the difference between actual length and $N_1 + N_2$, Q contains the actual length, both in octal.

Remedy: Start correct parameters or program later.

"limit" Fault: The symbolic program contains more than 245 different location symbols. The 245th symbol is in cell 06525, it may be found also from the last cards read.

Procedure: Go off the computer. Reduce number of symbols in program.

"trn tp" A=1.

Fault: A parity error is found while reading translated program from TU3 during assembly.

Remedy: Repeat assembly with another bias setting or with tape on another tape unit.

"ass tp" A=1

Fault: A parity error is found while reading back the assembled program from TU4 for verifying.

Remedy: Try another bias, another tape, or another tape unit for TU4. If MJ3 is off, start. Assembly is repeated. If MJ3 is on, go to 11.

A=5

Fault: Assembled program was recorded incorrectly on TU4.

Remedy: Start. A new recording will be attempted. Do not change tape or tape unit. Change of bias setting is permissible.

"excess" Fault: The program to be assembled, including sub-routines, exceeds core memory. There are two cases:

A=7200: The last word of the complete program will have an address greater than 07200.

A=7777 The temporary region required by the program exceeds core capacity.

Remedy: Repeat translation or assembly with lower ITA or IAA. Do not continue operation, because assembly routine will be clobbered.

C. Format of "assembly control card"

Only field I is used, fields II and III are ignored. Field I is again divided into 6 smaller fields, 6 columns each, which must contain the following information:

| Field | Columns | Contents |
|-------|---------|--|
| 1 | 1-6 | new name for program to be assembled. (program tag) |
| 2 | 7-12 | initial assembly address (IAA) in octal, up to 5 octal digits. Address may be anywhere in the field. |
| 3 | 13-18 | name of first program to be assembled. |
| 4 | 19-24 | } names of other programs to be assembled } together with the first one. Must be left } blank if not used. |
| 5 | 25-30 | |
| 6 | 31-36 | |

D. Incorporation of subroutines.

All subroutines to be used by a symbolic program must be in standard USE-format, i.e.,

- They must be stored on the drum.
- They must have the 5 parameters, N_1, N_2, N_3, P, R , stored directly in front of themselves.
- They must be coded relative to 01000.
- The normal exit must be two lines later than the entry line.
- The subroutine must be self-contained.

In the symbolic program a subroutine is referenced by its name or symbol. The translation will replace it by an octal symbol, a number between 30400 and 30777. A subroutine referencing another one will do so by using this octal symbol.

For each subroutine we have now 3 items:

1. Name or symbol, to be stored in DS-region
2. Octal symbol, to be stored in DA-region
3. Drum location, to be stored in DL-region

How to put these into the Trans-Use-1 routine may be best explained by an example. Assume we have the following 4 subroutines.

| Name | Drum Location | Highest Reference | Cells to be reserved for octal symbol |
|------|---------------|-------------------|---------------------------------------|
| SS1 | 40200 | SS1 + 3 | 4 |
| SS2 | 43000 | SS2 + 11 | 12 |
| SS3 | 40500 | SS3 + 2 | 3 |
| SS4 | 40600 | SS4 + 4 | 5 |

The number of cells in the last column is determined by the number of controls of the subroutine. It must be at least 3, because the normal exit is the 3rd line always. The regions DS, DL and DL have the drum addresses 61756, 62045, and 60210 respectively. The cells to be filled for our example are therefore:

| Address | Contents | remarks |
|---------|---------------|--|
| 61756 | 00 0000656504 | name of 1 st subroutine, SS1 |
| 61757 | 00 0000656505 | SS2 |
| 61760 | 00 0000656506 | SS3 (DS) |
| 61761 | 00 0000656507 | SS4 |
| 62045 | 00 0000030400 | Octal symbol of SS1 |
| 62046 | 00 0000030404 | " " SS2 |
| 62047 | 00 0000030420 | " " SS3 (DA) |
| 62050 | 00 0000030423 | " " SS4 |
| 62051 | 00 0000030430 | Octal symbol of future subr. |
| 60210 | 00 0000040200 | } Locations of subroutines in library (DL) |
| 60211 | 00 0000043000 | |
| 60212 | 00 0000040500 | |
| 60213 | 00 0000040600 | |

Note that the next free octal symbol must be filled in the DA-region. Up to 49 subroutines can be handled.

Talmadge

SUBJECT: APL Floating Point to Stated Point Conversion Subroutine

This subroutine converts a decimal floating point number in excess 3 form in two 1103A words to a stated point number in excess 3 form in two 1103A words.

The format of the decimal floating point number is as follows:

First 1103A word $\triangle M_1 M_2 M_3 M_4 M_5$
 Second 1103A word $M_6 M_7 M_8 \pm C_1 C_2$

where

- a. the sign of the mantissa is represented by the symbol \triangle (octal 01) if positive,
- b. the sign of the mantissa is represented by the symbol $-$ (octal 02) if negative,
- c. the eight digit mantissa is equal to or greater than 0.1 but less than 1.0,
- d. the sign of the characteristic is represented by the symbol $+$ (octal 63) if positive, and
- e. the sign of the characteristic is represented by the symbol $-$ (octal 02) if negative.

This subroutine will convert to stated point numbers only those floating point numbers in which $c_1 = 0$. If $c_1 \neq 0$, the floating point number is transferred to the output without conversion. When conversion occurs the format of the stated point number is as follows:

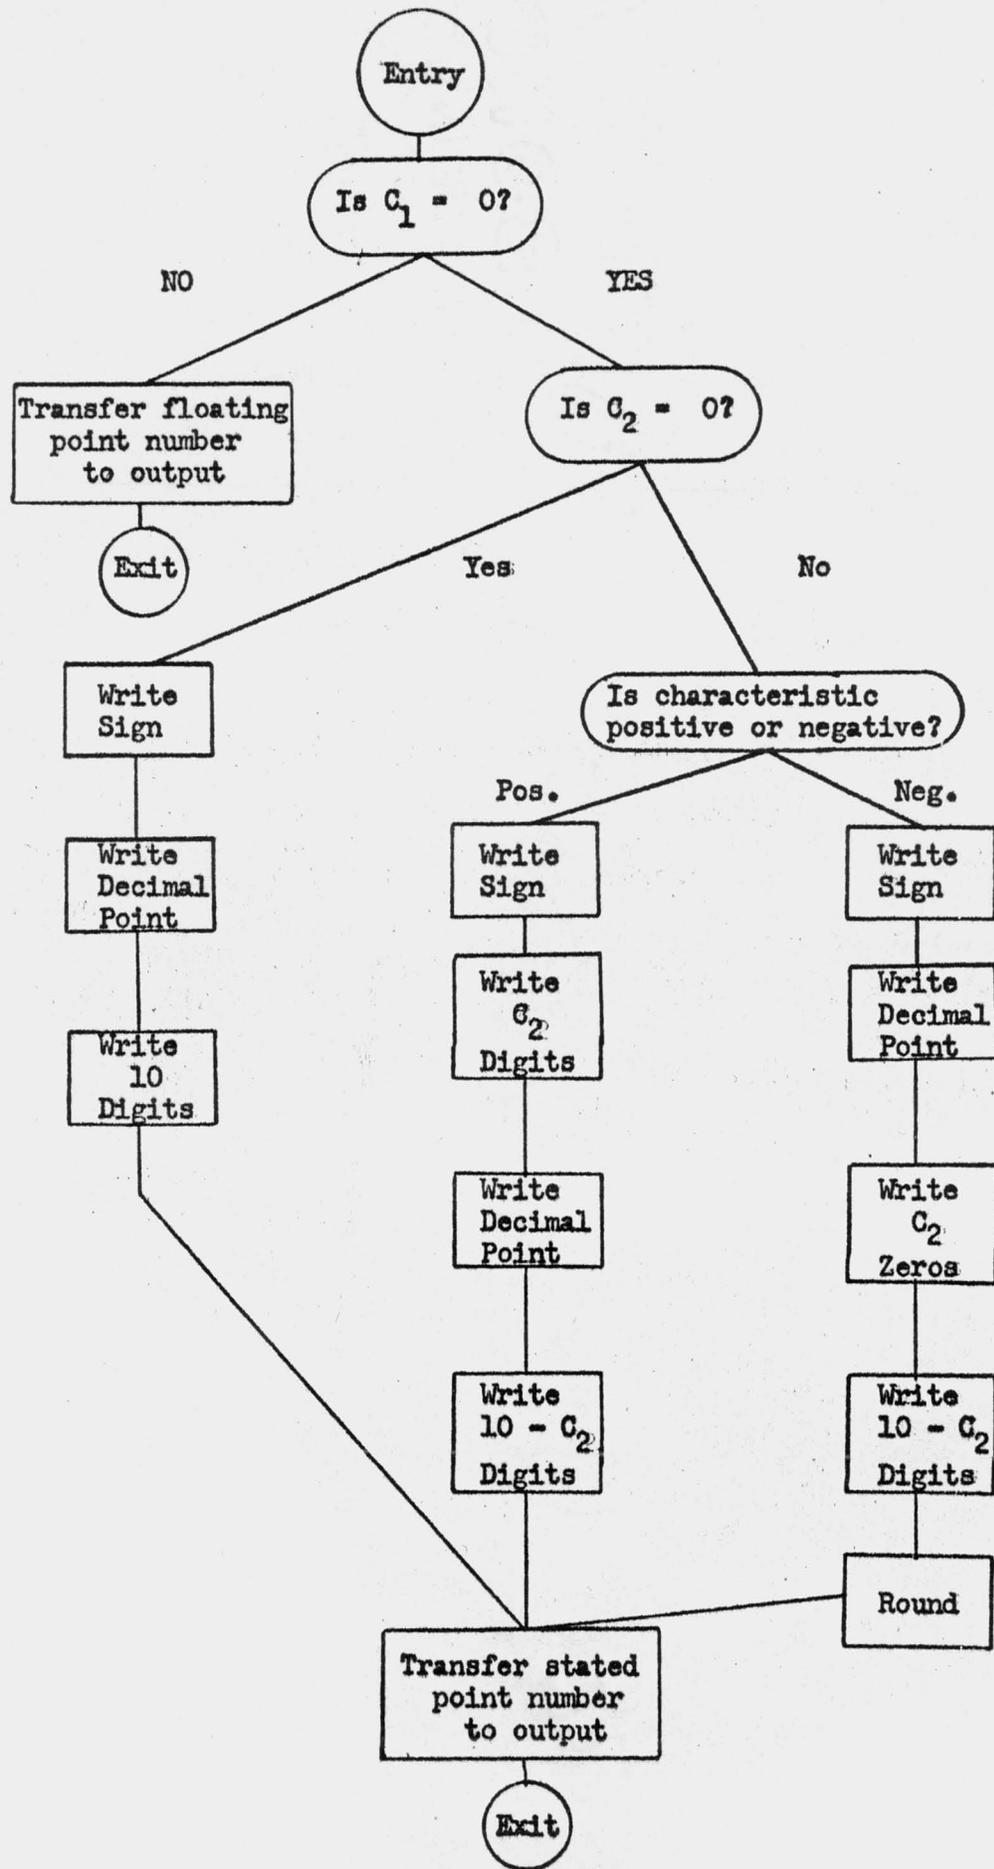

| <u>Decimal Characteristic</u> | <u>First 1103A Word</u> | <u>Second 1103A Word</u> |
|-----------------------------------|------------------------------------|--|
| -9 | $\triangle .0 \ 0 \ 0 \ 0$ | $0 \ 0 \ 0 \ 0 \ 0 \ \overline{M_1}$ |
| -8 | $\triangle .0 \ 0 \ 0 \ 0$ | $0 \ 0 \ 0 \ 0 \ M_1 \ \overline{M_2}$ |
| -7 | $\triangle .0 \ 0 \ 0 \ 0$ | $0 \ 0 \ 0 \ M_1 \ M_2 \ \overline{M_3}$ |
| -6 | $\triangle .0 \ 0 \ 0 \ 0$ | $0 \ 0 \ M_1 \ M_2 \ M_3 \ \overline{M_4}$ |
| -5 | $\triangle .0 \ 0 \ 0 \ 0$ | $0 \ M_1 \ M_2 \ M_3 \ M_4 \ \overline{M_5}$ |
| -4 | $\triangle .0 \ 0 \ 0 \ 0$ | $M_1 \ M_2 \ M_3 \ M_4 \ M_5 \ \overline{M_6}$ |
| -3 | $\triangle .0 \ 0 \ 0 \ M_1$ | $M_2 \ M_3 \ M_4 \ M_5 \ M_6 \ \overline{M_7}$ |
| -2 | $\triangle .0 \ 0 \ M_1 \ M_2$ | $M_3 \ M_4 \ M_5 \ M_6 \ M_7 \ M_8$ |
| -1 | $\triangle .0 \ M_1 \ M_2 \ M_3$ | $M_4 \ M_5 \ M_6 \ M_7 \ M_8 \ 0$ |
| 0 | $\triangle .M_1 \ M_2 \ M_3 \ M_4$ | $M_5 \ M_6 \ M_7 \ M_8 \ 0 \ 0$ |

| <u>Decimal Characteristic</u> | <u>First 1103A Word</u> | <u>Second 1103A Word</u> |
|-----------------------------------|-----------------------------------|------------------------------|
| +1 | $\triangle M_1 \cdot M_2 M_3 M_4$ | $M_5 M_6 M_7 M_8 \bar{0} 0$ |
| +2 | $\triangle M_1 M_2 \cdot M_3 M_4$ | $M_5 M_6 M_7 M_8 0 \bar{0}$ |
| +3 | $\triangle M_1 M_2 M_3 \cdot M_4$ | $M_5 M_6 M_7 M_8 0 0$ |
| +4 | $\triangle M_1 M_2 M_3 M_4 \cdot$ | $M_5 M_6 M_7 M_8 0 0$ |
| +5 | $\triangle M_1 M_2 M_3 M_4 M_5$ | $\cdot M_6 M_7 M_8 0 0$ |
| +6 | $\triangle M_1 M_2 M_3 M_4 M_5$ | $M_6 \cdot M_7 M_8 0 0$ |
| +7 | $\triangle M_1 M_2 M_3 M_4 M_5$ | $M_6 M_7 \cdot M_8 0 0$ |
| +8 | $\triangle M_1 M_2 M_3 M_4 M_5$ | $M_6 M_7 M_8 \cdot 0 0$ |
| +9 | $\triangle M_1 M_2 M_3 M_4 M_5$ | $M_6 M_7 M_8 0 \cdot 0$ |

where

- a. the sign of the number is represented by the symbol \triangle (octal 01) if positive,
- b. the sign of the number is represented by the symbol $-$ (octal 02) if negative, and
- c. the bar over the last digit indicates that the number has been rounded.

A general flow chart and the coding (not machine checked) in the APL format is enclosed.

USEful Note #10

10 April 1957

SUBJECT: Specifications of D.T.M.B. Omnibus Tape
Handling Routine for the Univac I Computer.

CONTRIBUTOR: RR

UNIVAC MEMO
No. 114

DATE: June 7 1956
DTMB SERVICE ROUTINE
F. E. Holberton

Navy Department
David Taylor Model Basin
Applied Mathematics Laboratory

D.T.M.B. OMNIBUS*

Programmed by N.Y.U.

Reprogrammed and extended by S.E. Kenady and F. E. Holberton DTMB

The D.T.M.B. Omnibus is a general utility service system, designed to incorporate into a single routine those functions frequently required in preparation and correction of information stored on tape. All sub-routines are performed using the standard UNIVAC G-10 code.

* Supercedes all other Omnibus writings.

| Example of Control Tape | 27 |
| Appendix | |

DESCRIPTION The D.T.M.B. Omnibus will perform 18 independent functions from control words manually typed at the computer, or previously prepared on a control tape. Some of the more frequently used functions are:

| | | |
|------------------------------------|---|--------------------------------|
| COPY BLOCKS | CORRECT SINGLE OR CONSECUTIVE WORDS IN BLOCKS | |
| COMPARE BLOCKS | FORWARD OR BACKWARD | MEMORY CLEAR AND INITIAL READ |
| SKIP BLOCKS | FORWARD OR BACKWARD | SEARCH BLOCKS, THEN COPY |
| REWIND TAPES | WORD SEARCH | COPY BLOCKS WHILE SEARCHING |
| SAMPLE BLOCKS OR BLOCKETTES | | SELECT AND MERGE DATA BY WORDS |
| VERIFY TWO UNITYPED TAPES | | HIGH SPEED PRINTER COEDIT |
| DIGIT CHANGE BY EXTRACTION PATTERN | | STOP |

Functions which produce selected output, such as discrepancies in comparison or sampled data, may be printed on the Supervisory Control Printer or written on tape. Information, if written on tape, is prepared for printing on the High Speed Printer using a Memory Dump board (10 words across with word spacing).

Many functions can be completely described by a single control word of 12 digits. The first character in the control word specifies the function the Omnibus routine is to perform. The interpretation of the remaining 11 digits is dependent upon the function performed. Wherever possible the format of the remaining 11 digits has been standardized. The standard control word format is as follows:

| | |
|--------|---|
| digit | |
| 1 | Control function |
| 2 | Input Servo number |
| 3 | Output Servo number |
| 4 | Supervisory control or Servo number for discrepancies during comparison |
| 5 | Specification for rewind of input servo |
| 6 | Specification for rewind of output servo |
| 7 | Write density for output servo |
| 8 | Optional comparison of input with output tape (combine with digit 4) |
| 9 - 12 | Number of blocks |

Some functions require additional information to be supplied in order to perform the operation. The additional information is in the nature of a sub-function and/or a quantity. Functions and sub-functions are interpreted by the Omnibus routine to perform certain operations, but quantities are information supplied as word substitutions.

| | | |
|-----|--------------|--|
| eg. | Function | Copy with corrections |
| | Sub-function | Block and word number of correction |
| | Quantity | (Word to be substituted for existing word) |
| | Sub-function | End of corrections |

CONTROL

1. Manual. Control words may be typed manually at the keyboard after the routine prints CONTROL WD. If a function requires additional information, appropriate words will be printed on the S.C. Printer before any request for a type in is made. At the conclusion of any function except the Initial Read and Stop functions, the routine will ask for another CONTROL WD.

2. Control Tape. Control words may be previously prepared on a tape in the order of their desired execution. The last valid control function on a Control Tape must be either an Initial Read or a Stop function. The Control Tape may be mounted on any UNISERVO except minus (-). Set the Conditional Transfer Breakpoint corresponding to the Control Tape UNISERVO number. Clear C, and input ready light if set, and actuate the start bar. The routine will stop on the Breakpoint set. FORCE TRANSFER on the Breakpoint will cause the routine to print TAPE CONTROL and proceed to read the Control Tape and perform the functions specified on the Control Tape. Tape (u), if used in any of the control functions, and the Control Tape will be automatically rewound with interlock when interpreting a Stop or an Initial Read function on the Control Tape. No Rewind control functions are required to rewind the Control Tape or Tape (u).

TO START THE CONTROL TAPE AT OTHER THAN THE BEGINNING, SET BKPT. 6, after selecting the Tape Control Breakpoint. The first word on the Control Tape will be printed on the S.C. Printer and the computer will stop on BKPT. 6. FORCE TRANSFER on BKPT. 6 will cause the following print out to appear: BLK AND WD OF CONTR WD. Type in the block and word number of the location containing the desired starting control word in the following form: 00bbbb 0000wd. Release BKPT. 6. The Control Tape will be rewound without interlock and read forward to the block and word specified by the type in. The Control Tape will be processed starting with the specific control word located.

TO CHANGE A CONTROL WORD ON THE CONTROL TAPE SET BKPT. 5. The computer will stop after printing each control word about to be processed. If a FORCE TRANSFER on BKPT. 5 is performed, the routine will print out TYPE NEW WD and set up a type in. Type in a control word to replace the last control word printed. BKPT. 5 cannot be used to change an incorrect sub-control function.

OPERATING INSTRUCTIONS

Omnibus Instruction Tape -- Any servo, if using DTMB Service Routine Locator which automatically changes all servo "IS" instructions to "A" servo number. THE INITIAL TAPE SELECTOR BUTTON MUST REMAIN SET TO THE SERVICE ROUTINE TAPE NUMBER AT ALL TIMES. The following control words will cause the Service Tape to be read to locate the necessary subroutines: H, K, L, Q, V, and W. At the conclusion of the subroutines, or a clear C operation, the Omnibus routine is read back into the memory. The Service Routine Tape is rewound without interlock after any reading of the Omnibus routine or its externally stored subroutines.

Block Subdivider Button -- If tape output is used (a non zero digit typed as digit four of a control word) see notes on Tape u. No print out to instruct the operator of this condition is made. The H. S. P. Codedit routine (H) will instruct the operator to set the appropriate Block Subdivider Button and Stop.

Breakpoints -- A few breakpoints may be used during the processing of certain control functions.

BKPT 5, BKPT 6, and Control Tape number -- see Control Tape

BKPT 1 -- See Search, and Copy While Searching

BKPT 9 -- See Word Changer

BKPT 3 -- See H. S. P. Codedit

BKPT 0, 1, comma, and Tape number -- See Verify

BKPT 5 -- See Line Merge

BKPT 7 -- See Copy with Corrections

Notes to the Operator.

The Initial Read Function (I) is the only control word which destroys the Omnibus Routine in the memory.

The Omnibus Routine may be used for both control tape and manual option. It should not be necessary to Initial Read the Omnibus Routine into the memory between consecutive users, no matter which option is used.

The Clear C operation will reset the Omnibus Routine to the original conditions, with the exception of the block counter and the location storing the presence of tape u during any set of control words. The presence of tape u is cleared only by a Stop function. A Clear C operation may be performed at any time, except during the reading of the Service Tape.

Clear C to set the Breakpoint option for the Control Tape, if the last word printed was "CONTROL WD." Clear the Input Ready signal before proceeding. The Control Tape Breakpoints are sequenced for execution before the print out of "CONTROL WD".

7.

The "R" control word will not rewind tape u as long as it is remembered in the memory. The Stop function resets this memory location to zero and rewinds tape u with interlock. If it is necessary to rewind tape u because of computer trouble, Clear C to bring up the CONTROL WD and type in the "R" function with tape u specified as the 4th zone alphabetic equivalent of the numeric tape number or rewind the tape manually.

Any control word which makes use of tape u will complete the last partial block stored in the memory and write the data on tape u at the conclusion of the control function.

If it is necessary to determine the block counter after the inability to read a designated number of blocks - Clear C and bring up the CONTROL WD. Type in 500901 000000 as the control word. Memory location 901 will contain the number of blocks read correctly, and copied, if specified by the process.

Storage locations within Omnibus for Specific Information

| | |
|------------------------------|--|
| Block Counter | 901 |
| Block Limit | 902 |
| Control Word | 903 |
| Input Block (tape s) | 500-599 and output for Z, X, W Q and K |
| Second Input Block (tape s2) | 560-619 for C, C, and V |
| Control Tape Input | 620-679 |
| Output Tape Option (tape u) | 700-759 |

RERUN

Clear C, and Input Ready if the neon is lighted. Register I is normally empty at the completion of any control word except the Initial Read Function.

The Clear C operation will reset the Omnibus Routine to the original conditions. USE ONLY IN CASE OF ERROR OR TO PROCEED THROUGH CONTROL TAPE BREAKPOINT OPTION.

When the computer stops on a normal Stop Instruction DO NOT CLEAR C OR rI. The computer has been stopped after printing specific instructions to the operator on the S. C. Printer or from a stop control word or an Initial Read control word.

The actuation of the Start Bar after a Stop control function will send control to 000.

The actuation of the Start Bar after an Initial Read control word will transfer the contents of rI to 000-059 and send control to 000.

Do not Clear C if an error has been made during the reading of the Omnibus Routine into the memory from the Service Tape. The Clear C operation may be momentarily non operative when searching for certain control function subroutines.

6

NOTES ON THE USE OF THE OPTIONAL TAPE OUTPUT - TAPE u

Six control words can make use of the optional tape u output. These are C, D, S, W, X and Z. The information written on tape u is prepared for printing on the High Speed Printer using a memory dump board. If the data contains no multi-line or fast feed symbols, it can be printed on NORMAL for best results. The C, D, W, X, and Z control words use three words in the blockette for: the old word, block and word number, and the new word. The related servo numbers are listed in the heading. The remaining words in the blockette are filled with spaces.

The sample routine (S) will make use of one, two, six or seven words in the blockette, depending upon the choice of digits 3 and 6 in the S control function. Sampling a block without listing the block number will print one word, or six words if sampling blockettes. If the block number is printed, two or seven words of the blockette will be used when sampling blocks and blockettes respectively.

At the completion of any control function using tape u, the partial block in the memory is filled with spaces and written on tape u, so that the pertinent information will be on tape when entering a new control sequence.

The blocks written on tape u are written at 100/in. density and are not counted, so that care must be exercised by the user not to exceed 1250 blocks.

The Omnibus routine does not remind the operator to set the Block Subdivider Button when specifying tape u. When the fourth digit of the above control words is not zero, the appropriate Subdivider Button must be set.

It has been assumed that the same servo number will be used for tape u, by the programmer on any sequence of operations requesting optional output. If it is desired to vary the servo number for tape u during a sequence of operations, it must be remembered that only the last tape number used will contain a Printer Stop at the end of the tape and be automatically rewound when a Stop function is given. The other tapes will not contain a Printer Stop symbol, but can be rewound with the R control word after a new tape u number has been initiated.

Tape u will not respond to the R control function even when called for. This safeguards any accumulated output from being destroyed by an operator error in typing an incorrect tape rewind control function.

12

If it is necessary to restart the process and rewind tape u, type in a Rewind control function and specify the servo u number by the 4th zone alphabetic equivalent of the servo number or rewind tape u manually.

Never use tape u for the output for the H. S. P. Codedit. The H. S. P. Codedit requires a special plugboard and rewinds both input and output tapes before starting the codedit, which would destroy any previous data on tape u.

13

COPY WITHOUT CORRECTIONS

Z s t u r_g r_t d c b b b b

COPY [Z] from tape (s) to tape (t) (bbbb) blocks at (d) density.

d = 0 for 100/in., d ≠ 0 for 20/in. density.

If digit c is greater than zero, compare tapes (s) and (t) word by word reading in the backward direction. No discrepancies should occur. If the two tapes differ, the words which differ, together with the block and word number of each discrepancy will be either written on tape or printed on the Supervisory Control Printer as specified by digit u.

u = 0 Print on S. C. Printer

u ≠ 0 Write on Tape (u) (u) must be 1 to 9 or -. Set Block Subdivider u.

The r digits control the rewind options for the input (r_g) and output (r_t) tapes.

r = 0 Do not rewind tape. Reposition tape bbbb blocks forward if comparison has taken place.

r = 6 Rewind tape without interlock.

r = 8 Rewind tape with interlock.

COPY WITH CORRECTIONS

X s t u r_g r_t d c b b b b

COPY WITH CORRECTIONS [X] from tape (s) to tape (t) a total of (bbbb) blocks at (d) density. d = 0 for 100/in., d ≠ 0 for 20/in. density. A list of corrections together with the block and word number of the corrections, terminated by a word of all Z's will follow the control function.

If digit c is greater than zero tapes (s) and (t) are compared word by word reading in the backward direction. The words which differ, together with the block and word number of each discrepancy will be written on tape or printed on the Supervisory Control Printer as specified by digit u.

u = 0 Print on S. C. Printer

u ≠ 0 Write on tape (u) (u) must be 1 to 9 or -. Set Block Subdivider u.

The r digits control the rewind options for the input (r_g) and output (r_t) tapes.

r = 0 Do not rewind tapes. Reposition tape bbbb blocks forward if comparison has taken place.

r = 6 Rewind tape without interlock.

r = 8 Rewind tape with interlock.

Sub-control words

n n x x x x 0 0 0 0 y y

n n Number of consecutive corrections listed under the Sub-control word
nn = 00 or 01 for a single word correction. Consecutive corrections must be within the block number listed.

x x x x Block number

y y Starting word number for corrections
End of corrections.

Z Z Z Z Z Z Z Z Z Z Z Z

When using the nn digits to specify a consecutive list of corrections, follow the subcontrol word with nn QUANTITIES to be supplied as corrections. The block and word number represent the location of the first correction. When operating from manual control, the first old word will be printed on the S. C. Printer, and nn consecutive "input ready" signals will be set up without printing the consecutive old words.

NOTE: All subcontrol words must be listed in ascending order by block number.

When a subcontrol word from a Control Tape specified a consecutive list of corrections and the nn digits, describing the number of corrections, have been typed incorrectly, the routine may attempt to decode a QUANTITY as a subcontrol word and produce one of two kinds of errors.

1. Adder Alpha

The routine has attempted to add digits 1 and 2 to 11 and 12 of a Quantity instead of a subcontrol word. Digits 1 and 2 are added to 11 and 12 of a subcontrol word to determine if $nn + yy$ is > 60 .

Remedy: Set BKPT 7

SCI_{CR} 000000 U00224

Proceed as for CHECK ORDER Remedy.

2. CHECK ORDER printed, followed by a QUANTITY rather than a subcontrol word.

Remedy: If the word printed out after CHECK ORDER is not a subcontrol word, but a QUANTITY, and the QUANTITY is either the 2nd consecutive correction word when nn was typed as 00, or the nn + 1st consecutive correction where nn was less than the number of corrections, the following insertions may be made:

Set BKPT 7

Type in a new subcontrol word ~~nnxxxx~~0000yy

Where yy is the location of the printed QUANTITY, nn is the number of corrections to be made, and xxxx is the same block number as the previous subcontrol word.

FORCE TRANSFER on BKPT 7 to cause the routine to use the type in as an insertion, rather than a replacement. A word of all "Z's" may not be typed as an insertion when using BKPT 7. See Control Tape BKPT 6 option.

COMPARE FORWARD

C s₁ s₂ u r_{s1} r_{s2} 0 0 b b b b

COMPARE [C] tapes (s₁) and (s₂) reading in the forward direction (bbbb) blocks. If any differences occur between tapes (s₁) and (s₂) record the word from tape (s₁), the block and word number, and the word from tape (s₂) on the Supervisory Control Printer if digit u = 0. If digit u ≠ 0 write discrepancies on tape (u). u ≠ 0 must be 1 to 9 or -. Set Block Subdivider u. The r digits control the rewind option for tapes (s₁) and (s₂).

- r = 0 Do not rewind tape.
- r = 6 Rewind tape without interlock.
- r = 8 Rewind tape with interlock.

COMPARE BACKWARD

D s₁ s₂ u r_{s1} r_{s2} 0 0 b b b b

Same as COMPARE FORWARD except tapes are read and compared in the backward direction. All discrepancies are listed in a descending order with the first block read in backward as block bbbb and the last block read as 0001. The tapes are not repositioned forward if rewind is not specified.

SKIP FORWARD

F s 0 0 0 0 0 0 b b b b

SKIP FORWARD [F] (read in the forward direction) on tape (s) (bbbb) blocks.

SKIP BACKWARD

B s 0 0 0 0 0 0 b b b b

SKIP BACKWARD [B] (read in the backward direction) on tape (s) (bbbb) blocks.

REWIND TAPES WITHOUT INTERLOCK

R s s s s s s s s s a 0

REWIND [R] the tapes specified by the digits s. Digits (s) must be 0, 1 to 9 or -. Any number of tapes may be rewound with a single control word. Fill the unused digit positions with zero. It is not necessary to type the servo numbers in any special order and zeros may be interspersed.

If tape u has been written on at any time during the use of the Omnibus routine, the "R" control function will omit the rewinding of this tape even though called for. This safe guards the information on tape u from receiving a Printer Stop block which would destroy the first block on the tape if allowed to rewind. The Printer Stop is automatically supplied when a STOP OR INITIAL READ control function is executed, and tape u is rewound with interlock.

NOTE: It is never necessary to rewind the control tape (if used) or tape u. This operation is performed automatically at the execution of a STOP or INITIAL READ function.

MEMORY CLEAR, INITIAL READ

I s a 0 0 0 0 0 0 0 0 0 0

Clear the memory to zero if digit a = 0. If digit a ≠ 0, clear the memory to Stop Instructions with the address of line number inserted in the stop instruction. e.g. 900060 900060

900999 900999

Read one block from Tape (s) into rI. The computer will Stop. Actuation of the start bar will cause (rI) to go to 000-059 and control will be transferred to line 000. The Omnibus Routine has been destroyed.

If tape (u) has been specified during any previous Omnibus Control function, the Initial Read function will cause a Printer Stop block to be written on Tape (u) and Tape (u) will be rewound with interlock.

If a control tape has been used, the Initial Read Function will cause the control tape to be automatically rewound with interlock.

The last control word for either manual or control tape option should be an Initial Read or a Stop function.

STOP

9 9 9 9 9 9 9 9 9 9 9 9

The control tape, if used, will be rewound with interlock. Tape (u), if previously specified, will receive a Printer Stop block and be rewound with interlock. The computer will be stopped. The Omnibus routine is reset to the initial condition and the storage for control tape and tape(u) are cleared.

Actuation of the start bar will send control to 000 (same as a Clear C operation).

The last control word for either manual or control tape option should be a Stop or an Initial Read function.

SKIP - NO OPERATION

0 0 0 0 0 0 0 0 0 0 0 0

Omnibus will perform a skip operation during a tape control option only. It is used to delete control words from a control tape if certain functions are not to be performed, so that retyping of a control tape is not necessary.

SAMPLE

S s k u r_g x v w b b b b

SAMPLE [S] one word in each block or blockette, the location specified by digits (wv), from tape(s) for a total number of bbbb blocks. If digit x = 0, sample one word per block. If digit v sample one word per blockette. The sampled words will be printed on the S. C. Printer if digit u = 0 and written on tape (u) if u ≠ 0. Digit u must be 0, 1 to 9 or minus (-).

If digit k = 0 the block number of each sampled word will be omitted in the print out.

If digit k ≠ 0 the block number will appear for each new block sampled.

When the output is prepared for tape (u), one, two, six, or seven words will appear in each H. S. Printer blockette, depending upon the specifications for digits k and x.

Sampling by blocks will produce either one, or two words per output line.

Sampling by blockettes will produce either six or seven words per output line. When sampling blockettes, digits (wv) must lie between 00 and 09, which specifies the word position within the blockette, to sample correctly.

The r digit controls the rewind option for the input tape s.

- r = 0 Do not rewind Tape s.
- r = 6 Rewind Tape s without interlock.
- r = 8 Rewind Tape s with interlock.

PRINTOUT OR BLOCKWRITE

5 0 0 m m m 0 0 0 0 0 0

The "5" control word is primarily provided to aid the operator in determining the block counter number, without manually setting up the Static Register, when a tape cannot be read to its specified block limit.

Clear C and type in control word 500901 000000 will cause this instruction word to be executed and the block counter in 901 will contain the number of the last correct block read (and written if during copy).

The control word may be used to write a block of zeros on a tape if typed as 5n0700000000 provided no output tape u option has been performed which uses 700-759 as the output block, and the H, V or W functions have not been performed since the last memory clear operation.

The second instruction in the word may be used for a limited selection. e.g. 00, 10, 50 or 5n instruction.

SEARCH, THEN COPY WITH CORRECTIONS

Q s t 0 r_s r_t w w b b b b

Follow the control word with a 12 digit QUANTITY on which the search is made. The search is made on all 12 digits.

- ww > 59 All words are searched
- ww ≤ 59 Only one word, as specified, in block is searched
- bbbb Number of blocks to be copied with corrections, including the block containing the searched word.

SEARCH [Q] on tape (s) until the 12 digit QUANTITY supplied is equal to the searched word in location (ww), then copy with corrections from tape (s) to tape (t) (bbbb) blocks, starting with the block containing the searched word. Follow the QUANTITY with the sub-control words for COPY WITH CORRECTIONS. Tape (t) is written at 100/in. pulse density.

The r digits control the rewind options for the input (r_s) and output (r_t) tapes.

- r = 0 Do not rewind tape.
- r = 6 Rewind tape without interlock.
- r = 8 Rewind tape with interlock.

The block and word number of the searched QUANTITY will be printed on the S. C. Printer.

To SEARCH WITHOUT COPY Q s 0 0 r_s 0 w w 0 0 0 0 set the block number equal to zero. The block and word number of the searched QUANTITY will be printed on the S. C. Printer. Follow the QUANTITY specified for the search with the next control word.

If it is desired to search after the initial agreement of the QUANTITY and the searched data set BKPT 1 at the beginning of the search process. The block and word number will be printed and the computer will stop on BKPT 1. FORCE TRANSFER to continue the search process. This procedure may be continued as often as desired. If the word is never found on the tape, the tape will either stop on a two block read or if a blank tape beyond the data, will cause the tape to read off the end.

COPY - NO CORRECTIONS, WHILE SEARCHING

K s t O r_s r_t w w b b b b

Follow the control word with a 12 digit QUANTITY on which the search is made. The search is made on all 12 digits.

- ww > 59 All words are searched.
- ww ≤ 59 Only one word, as specified, in each block is searched.
- bbbb Upper limit of blocks copied while searching. If bbbb is reached without finding the search word, the routine prints out NO SUCH WORD and proceeds to the next control word.

COPY [K] from tape (s) to tape (t) while searching for agreement between the QUANTITY and the searched word in position (ww). Copy to and including the block containing the searched QUANTITY. Tape (t) is written at 100/in. pulse density.

The r digits control the rewind options for the input (r_s) and output (r_t) tapes.

- r = 0 Do not rewind tape.
- r = 6 Rewind tape without interlock.
- r = 8 Rewind tape with interlock.

The block and word number of the searched QUANTITY will be printed on the S. C. Printer.

If it is desired to copy and search after the initial agreement of the QUANTITY and the searched data, set BKPT 1 at the beginning of the search process. The block and word number will be printed and the computer will stop on BKPT 1. FORCE TRANSFER to continue the search process. This procedure may be continued as often as desired. If the word is never found on the tape when the upper limit block count (bbbb) is reached, the routine will print out NO SUCH WORD, perform the rewind option, and proceed to the next control word.

20
H. S. P. CODEDIT

H 0 0 0 0 0 0 0 0 0 0 0 0

The Omnibus Routine will call in the DTMB H. S. P. CODEDIT, which has been modified to be used as part of Omnibus, if desired. The control words performed by the CODEDIT are described in UNIVAC MEMO 111.

The control words associated with the CODEDIT must not exceed 60 words (not including the control function word H00000 000000), but may be split between blocks on a control tape.

At the completion of the CODEDIT, the Omnibus Routine is automatically called back and subsequent words on the control tape, if used, are performed.

If it is desired to type the control words for the CODEDIT in a separate block so that they may also be used by the ANALYZER routine for future processing, fill the block containing the "H" function with zero and compile the CODEDIT control words in the block following. The CODEDIT routine, if called in by an Omnibus control tape, will consider the first non zero word following the "H" function to be the date (the first CODEDIT control word).

The H. S. P. CODEDIT may be called in by a manual option from Omnibus but perform a control tape CODEDIT by setting BKPT 3 and FORCING TRANSFER when the CODEDIT has been located.

When performing a CODEDIT from an Omnibus control tape, the control words are assumed to be on the same control tape.

Do not use tape (u) as the output for the CODEDIT, because the input and output tapes are rewound at the beginning of the CODEDIT and any accumulated data on tape (u) will be destroyed. Information accumulated on Tape (u) from previous Omnibus control words will be printed using a memory dump plugboard and the output from the CODEDIT requires a special board.

Rerun: Clear C

When the CODEDIT has been called in from a manual control Omnibus, the Clear C operation will start the CODEDIT routine over again.

When the CODEDIT has been called in from an Omnibus control tape, the Clear C operation will recall the Omnibus routine and perform the general Omnibus Clear C function.

21

LINE MERGE -- COPY BY WORDS

L 0 t 0 0 r 0 0 0 0 0 0

The LINE MERGE routine permits information to be copied from many tapes to a single output tape on a word by word basis instead of a block by block basis. The control word specifies only the output serve number (s) and the output rewind option (r_t). r_t = 0, 6 or 8, do not rewind, rewind without interlock, or rewind with interlock, respectively. The remaining controls are performed by the subcontrol words which follow the control word.

The subcontrol words permit three options for copying data.

1. Copy from tapes (other than the control tape).
2. Type in data at the console, or transfer data from the control tape.
3. Fill a specified number of words, or to the end of the current output block, with a specific QUANTITY.

Sub control functions

| | | |
|---|---|---|
| M <u>BLK</u> <u>WD</u> s <u>blk</u> <u>wd</u> | - | Copy [M] from tape (s) starting with block and word number <u>BLK</u> <u>WD</u> to and including block and word number <u>blk</u> <u>wd</u> . |
| Ax0000 00nnnn | - | Add [A] (nnnn) words of the same pulse combination to the output tape. If x = 0, words of zero will be written. If x = Z, words of all Z's will be written. If x = Y, the QUANTITY specified by the word will be written on the output tape. |
| Ax0000 000000 | - | Fill to the end of the current output block with the QUANTITY specified by the x digit. If the previous block had been completely filled prior to the execution of the subcontrol word, a complete block of fill digits will be written each time the subcontrol word is given. |
| T00000 00nnnn | - | Transfer [T] the next nnnn words from the control tape, or type in nnnn words at the console (if on manual option) to the output tape. |
| ZZZZZZ ZZZZZZ | - | End of Line Merge. |

Failure to complete the information in the last output block when all Z's is supplied as a subcontrol word, will cause the routine to print out BLOCK NOT FULL and ask for a type in of a 12 digit QUANTITY which will be used to fill to the end of the current output block. The number of blocks on the output tape will be printed on the S. C. Printer.

No provision is made for rewinding the input tapes within the Line Merge subroutine, but may be supplied as a "R" control word after the word of all Z's.

The format of the "M" subcontrol word limits the input block number to three digits or 999 blocks.

When the Line Merge Control word is specified, the routine assumes that all 10 servos on the computer are (figuratively speaking) about to read block one. The routine remembers the number of blocks read from all servos, and will read the tape in the forward or backward direction to locate the starting block number, depending upon the previous operation on any specific servo (s). Block and word numbers are always specified in relation to their physical location on the tape and not related to the position of the reading head at any time except at the very beginning when each tape number, regardless of previous motion, is assumed to be at the block beginning for counting purposes.

Information may be copied any number of times from tapes and no restrictions are placed on switching from one input servo to another and back again.

The starting block and word number must be equal to or less than the ending block and word number for any single "M" subcontrol word. The routine assumes a minimum of one word will be copied when supplying the "M" subcontrol word. Failure to meet this requirement will cause the routine to print out CHECK ORDER and call for a type in of a subcontrol word to substituted for the error one.

If it is known in advance that a Line Merge subcontrol word on a control tape is in error set BKPT 5. Each subcontrol word (on the Line Merge only) is printed on the S. C. Printer before it is executed. The computer will stop on BKPT 5 after printing each subcontrol word. FORCE TRANSFER on BKPT 5 after the incorrect subcontrol word is printed. The routine will print out TYPE CONTROL. Type in a subcontrol word to replace the error. The Line Merge routine is the only routine which permits the correction of a subcontrol word in connection with BKPT 5. BKPT 5 is normally reserved for control word correction only.

WORD CHANGERW s t u r_s r_t d c b b b b

The Word Changer routine permits substitution of digits in the operation parts, the address parts of an instruction word, or in specified digit positions in a full word. Sub control functions specify the mode of examination, the digit quantities to be searched on, the extractor to be used in the comparison and the quantity to be substituted when equality is found.

The word changer routine may be used as a Code search operation, searching on as many as 47 different addresses simultaneously. The routine may be used to perform a variety of changes, such as changing all servo numbers, supplying a minus to all D, X, A or S instructions or changing a group of addresses when constants have been moved in the coding without listing each change independently with an X control word.

The complete list of subcontrol function words is stored in the memory at the beginning of the process. Each word on the input tape is compared against the list and appropriate changes are made when agreement is found.

Copy (bbbb) blocks from tape (s) to tape (t) making the designated changes described by the subcontrol list. Write on tapes (t) at pulse density (d). If d = 0, write at 100/in, if d ≠ 0, write at 20/in. density.

If digit c is greater than zero, compare tapes (s) and (t) in the backward direction, printing the differences on the S. C. Printer if digit u = 0, or on tape (u) if u ≠ 0. If c is = 0, no comparison will take place.

The r digits control the rewind options for the input (r_s) and output (r_t) tapes.

- r = 0 Do not rewind tape. Reposition tape bbbb blocks forward if comparison has taken place.
- r = 6 Rewind tape without interlock.
- r = 8 Rewind tape with interlock.

Sub-control words - For 1/2 word operation.

CCC OLD EEE NEW

- CCC = OPR if digits 1 - 3 and 7 - 9 (operation part of an instruction word) are to be examined.
- CCC = ARD if digits 4 - 6 and 10 - 12 (address part of an instruction word) are to be examined.
- OLD = Three digit quantity (of operation or address) on which the search is made.

EEE = Extractor pattern used to determine the equality of the old pattern and the insertion of the NEW. If all
 NEW = Three digit quantity which is used (in conjunction with EEE) to replace the OLD quantity.

ZZZ ZZZ ZZZ ZZZ End of list for modification.

Sub-control words - For full word operation

| | | |
|-----------------|-------------------|----------------------------------|
| CCC OLD EEE NEW | CCC = FULLWORDAAA | 12 digits for full word control. |
| | OLD = (|) 12 digits for old word. |
| | EEE = (|) 12 digit extractor |
| | NEW = (|) 12 digits for new word. |

Comparisons and substitutions are made by the extractor pattern of a full word. If all digits of the OLD word are to be compared, the extractor must be all ones.

ZZZ ZZZ ZZZ ZZZ End of list for modification.

A maximum of 47 sub-control function words (OPR, ADR, or FULL WORD) may be operated on at any time. Both full and 1/2 word controls may appear in the list.

Each sub-control set is separated into a 10 word item and stored in the computer. 47 such items, not including ZZZ ZZZ ZZZ ZZZ, may be used in a single list. If the number of subcontrol functions on a control tape exceeds this number the computer will print out LAST ITEM USED and the last subcontrol function used will be printed on the S. C. Printer. The control tape is then searched for the word of all "1's" and all intervening subcontrol words are not used.

The sub-control function is determined by examination of only the 2nd digit in CCC. OPR, ADR, FUL

On manual control, each old word, block and word number, and substituted word is printed on the S. C. Printer. If it is desired not to make a specific change, BKPT 9 should be set when approaching the specific block number. The routine will stop after printing the old word, and block and word number. FORCING TRANSFER on BKPT 9 will cause the routine to print SKIPPED and omit making the specific change on the output tape. This option is not available from control tape option, because the S. C. Printout of each change is omitted.

4. Or - Select none. Actuate the start bar without forcing any BKPTS.

The advancing of the input words for the next comparison is independent of the selection for the output. Either, both or neither may be stepped by forcing the breakpoint or breakpoints associated with the tape numbers. The selection precedes the advancing of the word in computer operations.

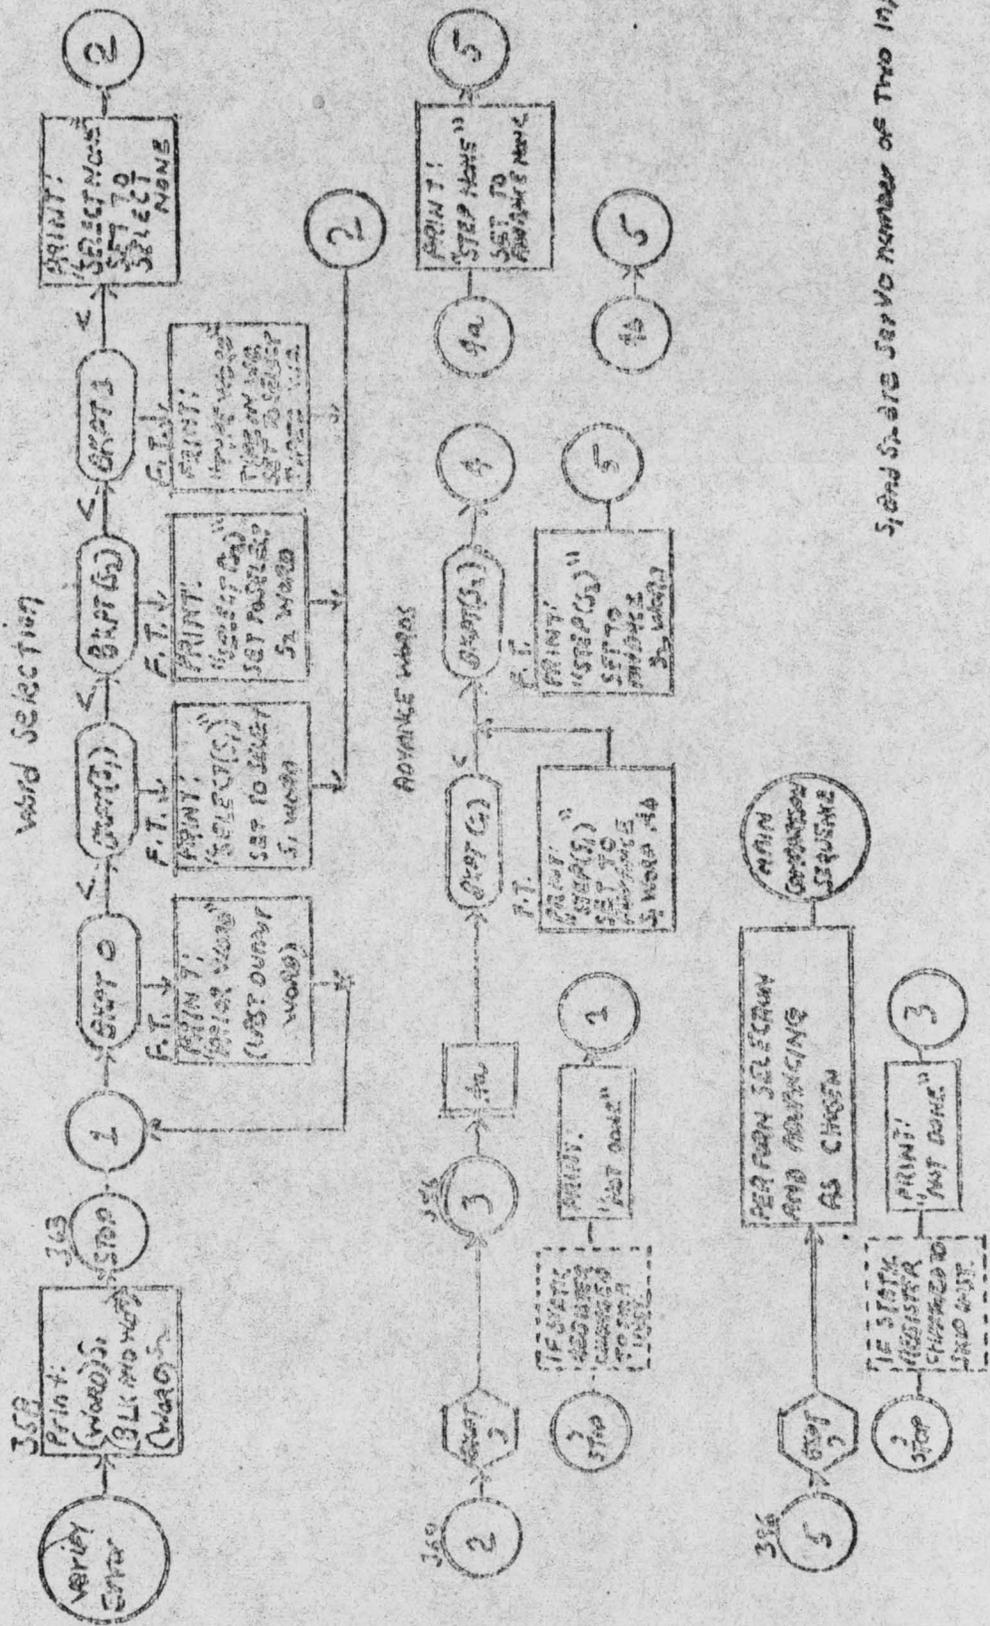

A complete record of all error words, and choices is recorded on the S. C. Printer. The routine will print out SELECT TAPE () of a word chosen and STEP TAPE () when a word is advanced. If BKPT COMMA (,) is not used, both Breakpoints referring to (s₁) and (s₂) should remain set at all times.

By setting BKPT COMMA (,) the computer will stop after printing each choice, but before the operation is actually performed. If the operator has forced the wrong BKPT., it is possible to correct his mistake. Set the correct BKPT and replace the instruction currently in the Static Register by a skip instruction. Actuation of the Start Bar will cause the routine to print NOT DONE and stop on the BKPT set and give the operator another chance to correct the error choice.

When omissions of data occur on both tapes at different locations, it is possible to complete the verify sequence with more words than were originally on the two input tapes and the last output block will be partially filled. Under this condition the routine will print out LAST VALID WORD and the contents of the last word. It will then print TYPE FILL and call for a type in of the QUANTITY to be used to fill the last output block. When the number of blocks on the output tape is not the same as the original input tapes, the new block count will be printed on the S. C. Printer.

The following flow chart is provided to clarify the Breakpoint procedure required to handle errors on tapes to be verified.

Verify Error Sequence with Breakpoint Options

Step 5: SET TO NONE

EXAMPLE OF OMNIBUS CONTROL TAPE

This control tape will combine parts of two old instruction tapes, change a few words and codedit the new tape produced. It will verify two untyped data tapes and add additional data from a previous data tape to the verified tape. It will sample the data tape, sending the block number and the second word of each blockette to the output on servo 9. Block subdividers for 8 and 9 are depressed. Tapes are mounted as follows:

| | | |
|-----------|---|---|
| Servo No. | 1 | Blank for instructions |
| " | " | 2 " " data |
| " | " | 3 Old instructions to be removed after rewind with interlock. Replace with tape to be verified. |
| " | " | 4 Old instructions (no ring) |
| " | " | 5 Old data tape |
| " | " | 6 Control tape (F.T. BKPT 6) |
| " | " | 7 Tape to be verified |
| " | " | 8 Blank for codedit |
| " | " | 9 " " tape option output |
| " | " | - Omnibus routine |

| <u>Word No.</u> | <u>Word</u> | <u>Purpose</u> |
|-----------------|---------------|--|
| 00 | Z41069 010002 | Copy instructions without corections from servo 4 to servo 1. Compare, rewind 4 without interlock, reposition 1. |
| 01 | X31980 010005 | Copy 5 blocks from servo 3 to servo 1. |
| 02 | 020001 000058 | Correct 3 successive words beginning in block 1 word 58. Compare and write the discrepancies on servo 9. Rewind servo 3 with interlock. Reposition 1. |

| 20 | OPR640 111630 | |
| 21 | FULLAW ORDAVV | |
| 22 | FEB.Δ1 6Δ1956 | |
| 23 | 111111 111111 | |
| 24 | JUNEΔ1 6Δ1956 | |
| 25 | ZZZZZZ ZZZZZZ | |
| 26 | H00000 000000 | CODEDIT 14 blocks on servo 4 with output on servo 8. |
| 27 | JUNEΔ1 6Δ1956 | |
| 28 | BASICA CODEΔ1 | |
| 29 | Z48000 000014 | |
| 30 | V37260 000045 | Compare the two tapes on servos 3 and 7 and write a verified tape on servo 2. Rewind 3 and 7 but leave 2 positioned for additional data. |
| 31 | Q52000 590015 | Search on tape 5 for a block containing 000000 15CD01 in word 59. Copy 15 blocks to tape 2 with no corrections. |
| 32 | 000000 15CD01 | |
| 33 | ZZZZZZ ZZZZZZ | |
| 34 | D52060 000015 | Compare 15 blocks backward on servos 5 and 2. Rewind servo 5. |
| 35 | F20000 000015 | Reposition servo 2 |
| 36 | K52060 590200 | Copy from tape 5 to tape 2 through a block containing 000000 16AC01 in word 59. The I.D. should be found within 200 blocks. Rewind tape 5. |
| 37 | 000000 16AC01 | |
| 38 | 520500 620000 | Copy the last block again and rewind tape 2. |
| 39 | S21961 020261 | Sample the second word of each blockette on servo 2. Include the block number in the output which will go on tape 9. Rewind 2. |
| 40 | 999999 999999 | Rewind tapes 9 and 6. Stop. |

Note: Since the programmer was not sure there were 200 blocks to be copied from servo 5 to servo 2 using the K function, he may wish to set breakpoint 5 during the K function. After S21961 090261 prints on SCP, he may force transfer on breakpoint 5 and adjust the block limit (261) by typing in a new control word.

SUMMARY OF SUB-CONTROL WORDS

COPY WITH CORRECTIONS (X s t u r_s r_t d c b b b b)
Sub-control words

| | | |
|-------------------------|---------|--|
| n n x x x x 0 0 0 0 y y | n n | Number of consecutive corrections listed under the sub-control word. nn=00 or 01 for a single word correction. Consecutive corrections must be within block number listed. |
| | x x x x | Block number. |
| | y y | Starting word number for corrections. |
| Z Z Z Z Z Z Z Z Z Z Z Z | | End of corrections. |

WORD CHANGER (W s t u r_s r_t d c b b b b)

Sub-control words - For 1/2 word operation.

| | | |
|---------------------|-----|---|
| CCC OLD EEE NEW | CCC | OPR if digits 1-3 and 7-9 (operation part of instruction word) is to be examined. |
| | CCC | ADR if digits 4-6 and 10-12 (address part of instruction word) is to be examined. |
| | OLD | Three digit quantity (of operation or address) on which the search is made. |
| | EEE | Extractor pattern used to determine the equality of the old pattern and the insertion of the NEW. If all three digits are to be examined EEE=111. |
| | NEW | Three digit quantity which is used (in conjunction with EEE) to replace the old pattern. |
| Z Z Z Z Z Z Z Z Z Z | | End of list for modification. |

Sub-control words - For full word operation.

| | | |
|-----------------|-------|---|
| CCC OLD EEE NEW | CCC | FULLWORDAAA12 digits for full word control. |
| | OLD (|)12 digits of old word. |
| | EEE (|)12 digits extractor. |
| | NEW (|)12 digits for new word. |

Comparisons and substitutions are made by extractor pattern on full word. If all digits of OLD are to be compared, extractor must be all ones.

End of list for modification.

A maximum of 47 sub-control function words (OPR, ADR, of FULL WORD) may be operated on at any time. Both full and 1/2 word controls may appear in the same list. (Each sub-control set is separated into 10 word items and 47 such items, not including ZZZ ZZZ ZZZ ZZZ, may be used in a single list.

The sub-control function is determined by examination of only the 2nd digit in CCC.

OPR, ADR, FUL

SEARCH, THEN COPY
WITH CORRECTIONS

(Q s t 0 r_g r_t w v b b b b)

w v > 59 All words are searched.

w v = 59 Only word specified is searched.

b b b b Number of blocks to be copied with corrections.

Follow the control word with a 12 digit QUANTITY on which the search is made. The search is made on all 12 digits. To continue search after initial agreement of QUANTITY and searched data, SET BKPT 1, FORCE TRANSFER.

Search, then copy - bbbb is the number of blocks to copy starting with the block containing the searched word. Follow the QUANTITY with the sub-control words for COPY WITH CORRECTIONS.

Search, without copy - bbbb is zero. Follow the QUANTITY with the next control word.

COPY - NO CORRECTIONS
WHILE SEARCHING

(K s t 0 r_g r_t w v b b b b)

w v > 59 All words are searched.

w v = 59 Only word specified is searched.

b b b b Upper limit of blocks copied while searching. If bbbb is reached without finding the search word, an appropriate printout will occur and the operation is terminated.

Follow the control word with a 12 digit QUANTITY on which the search is made. The search is made on all 12 digits.

To continue copy and search after initial agreement of QUANTITY and searched data, SET BKPT 1, FORCE TRANSFER.

Copy - to and including the block containing the search word.

LIVE MERGE
(COPY BY WORDS)

(L 0 t 0 0 r_t 0 0 0 0 0 0)

Sub-control words

M BLK WD s BLK WD

M

Control Digit - Copy.

BLK

Starting block number.

WD

Starting word number within block BLK.

s

Input servo number.

BLK

Ending block number.

WD

Last word in block blk copied.

A x 0 0 0 0 0 0 n n n n

A

Control digit - Add.

x

x=0 Add nnnn words of zeros to output.

x=Z " " " " all Z's to output. x

x=X " " " " the contents of which is specified by the QUANTITY which directly follows the sub-control word, to the output.

Fill to the end of the current output block with the quantity specified by x.

A x 0 0 0 0 0 0 0 0 0 0

T 0 0 0 0 0 0 0 0 n n n n

T Control digit - Transfer.

n n n n Transfer the next nnnn words from the control tape or manual typein to the output block and tape.

Z Z Z Z Z Z Z Z Z Z Z Z

End of Line Merge.

Failure to complete the information in the last output block will cause the computer to print out "BLOCK NOT FULL" and ask for a typein of the QUANTITY to be used as a fill.

When the LINE MERGE control word is specified, the routine assumes that all 10 servos on the computer are (figuratively speaking) about to read block 1. The routine remembers the number of blocks read from ALL servos. The tapes will read in the forward or backward direction to locate the starting block number, depending upon previous operation on servo 6. Information may be merged from many input tapes to a single output tape. No restrictions are placed on the sequence of data merged, except - the starting block and word number must be equal to or less than the ending block and word number for any single "M" sub-control word. Information is copied with the tape moving in the forward direction.

16 July 1956

Talmadge

USEful Note #11

29 April 1957

SUBJECT: Octal Card Load and Octal Dump

CONTRIBUTOR: HO

1. Identification

HOSR24, OCTAL CARD LOAD
Robert G. Tantsen, 12 Apr 57
Holloman Air Development Center
1103A-Service Routine

2. Purpose

To read any number of octal cards and store their contents on core or drum.

3. Method

- a. This is a service routine with manual and program entry. It bootstraps itself into core, and restores core upon exit.
- b. Each card is handled as a unit. The words are assembled in temporaries and then block-transferred to their destination.
- c. Checks are made to assure that:
 1. The card contains the identification punch
 2. The address is punched correctly
 3. Each word is punched correctly
- d. Under all circumstances the core is completely restored, including 00000, which need not have an MJ.

4. Usage

- a. Program entry is effected with the instruction RJ HOSR24+2, or, in abs. 37 44002 44000. Manual entry is done by starting at 40002.
- b. The routine exits upon finding a card without identification punch. On manual operation then PAK = 40002. After a successful exit (A)=0, (Q)=1.
- c. Space required (on drum) 88 cells. (HO-library:44000-44130).
- d. Error indications
Address: A correct address must have 5 octal digits. If not 5, or if an 8 or 9 appears, the typewriter prints "a". Card is not loaded, routine exits.

Words: Each word field on the card must have 12 octal digits punched, or be completely blank. If less than 12 digits, or 8's and 9's appear, typewriter prints "w". Card is not loaded, routine exits, computer stops with IO-fault. If a column is double punched, the higher digit will be read.

e. Input cards

The first card must be in reading position. If the routine is to be used repeatedly, the individual sections to be loaded must be separated by one blank card. Cards in each section may be in any order. Place 3 empty cards at end of whole card deck.

f. Card Format

Column: 1-12 first word in octal
13-24 2nd word
25-36 3rd word
37-48 4th
49-60 5th
61-72 6th word
73-77 insert address, 5 digits
80 a 5, identification punch

The address belongs to the first word, the others go into consecutive cells. If less than 6 words are needed, the fields not used must be left blank. There must always be a first word. Whenever a blank word field is detected, the information found so far is stored and the routine reads the next card.

5. Restrictions

- a. Attempt to load into cells exceeding the core capacity will cause an SCC-fault.
- b. Cells 77000-77200B are used for image purposes and should not be loaded, because they will be block-transferred back to 00000-00200B.

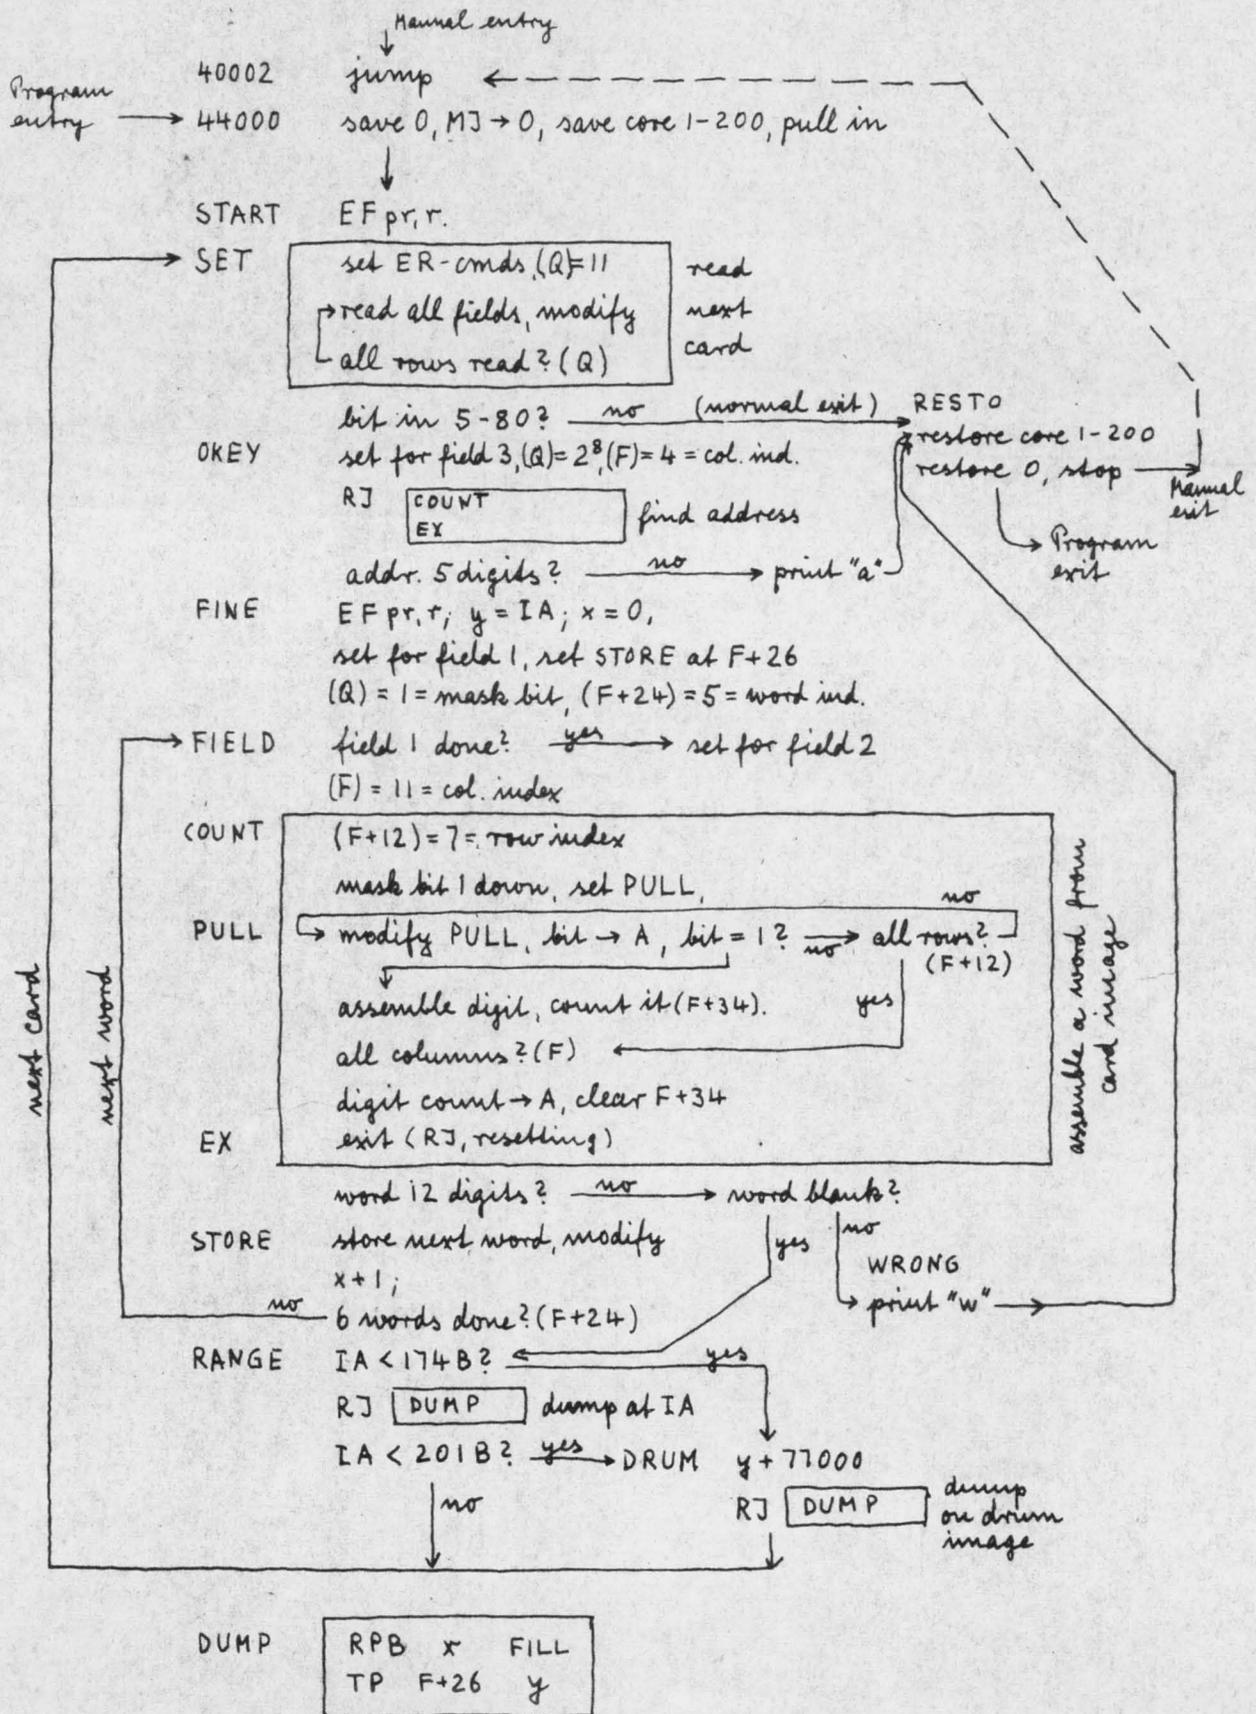

6. Coding Information

- a. Timing: Cards are processed at full Bull speed, 120 cards/min.
- b. Status: Routine is completely checked out.

Octal Card Load HOSR24

Flow Chart

1. Identification

HOSR14, OCTAL CARD DUMP
Paul D. Medley, 15 April 1957
Holloman Air Development Center
1103A-Service Routine

2. Purpose

To dump the contents of any number of consecutive cells on octal cards.

3. Method

- a. This is a service routine with manual and program entry. It bootstraps itself into core, and restores core upon exit, including cell 00000.
- b. The words to be dumped are transferred into temporary storage and punched out 6 words per card. This enables the Bull to operate at maximum speed.

4. Usage

- a. Program entry is effected by:

| <u>LOC</u> | <u>OP</u> | <u>U</u> | <u>V</u> | <u>REMARKS</u> |
|--------------------|-----------|---------------|----------|-----------------|
| y-2 | TP | FA | Q | First addr to Q |
| y-1 | TP | LA | A | Last addr to A |
| y | RJ | HOSR14+2 | HOSR14 | |
| y+1 | | NORMAL RETURN | | |
| at y+1 A and Q = 0 | | | | |

- b. Manual entry is effected by:

Set first address in Q_u
Set last address in $A(R)(u)$
Start at 40003

- c. The routine exits when the region has been punched. For manual entry $PAK = 40003$, A and Q = 0.

- d. Space required (on drum) 108 cells.
(HO-library 44131 -44327).

- e. Card format:

| | | |
|---------|-------|---------------------|
| Column: | 1-12 | first word in octal |
| | 13-24 | second word |
| | 25-36 | third word |
| | 37-48 | fourth word |
| | 39-60 | fifth word |
| | 61-72 | sixth word |

73-77 address, 5 digits
80 a 5 for identification

The address is associated with the first word, the other words are punched from consecutive cells. If less than 6 words are on a card the remaining columns for words are left blank. A zero word is punched all zeros.

- f. Cell 00000 may be dumped.
- g. A MJ for cell 00000 is not required.
- h. Cards punched with this routine may be reloaded with HOSR24.
- i. The Bull need not be cycled before punching and the channels are cleared after punching.

5. Restrictions

- a. Any attempt to dump an illegal address causes a SCC fault, or produces meaningless cards.
- b. Dump of A and Q is not permissible.
- c. Cells 76000B-77777B should not be dumped because they are used as core image. If they are dumped the cards have image addresses for information that was in 00000-01777B before entry.

6. Coding Information

- a. Timing: Cards are punched at maximum Bull speed except for a 1/4 sec. delay after each 128 cards.
- b. Status: This routine has been completely machine checked.

USEful Note #13

1 July 1957

SUBJECT: Parity Error Routine

CONTRIBUTOR: HO

Useful Note No.

1. Identification

HOSP11, PARITY ERROR ROUTINE
Robert G. Tantzen, 11 June 1957
Holloman Air Development Center
1103A Service Routine

2. Purpose

To recover from parity errors when reading magnetic tape, in fixed block mode, without computer stop.

3. Method

This is a service routine with program entry only. It can handle all cases where reading is done with a 120 times repeated ERB. So the main program may read forward or backward, free run or one block only. Re-reading is tried first on high, then on low bias. If one or the other attempt was successful, main program continues, the bias being reset to normal.

4. Usage

To use this routine, a calling sequence of three commands has to be inserted in the main program; this is two more than needed normally. A typical main program with calling sequence is given:

| LOC | OP | U | V | REMARKS |
|------|-----|----------|----------|----------------------------|
| KICK | EF | O | K | Start read |
| | : | | | |
| | : | | | |
| | : | | | |
| | RPV | 120 | READ+1 | |
| READ | ERB | O | XXX | Read 1 block |
| | ERA | O | A | |
| | ZJ | BAD | GOOD | Parity error? yes, no |
| BAD | TP | KICK | HOSP11+3 | Place controls |
| | TP | READ | HOSP11+4 | |
| | RJ | HOSP11+2 | HOSP11 | Go to parity error routine |
| GOOD | | | | Block read correctly |

If both attempts to re-read are unsuccessful, typewriter prints P TUX, where X is the tape unit number. The computer comes to a PS stop.

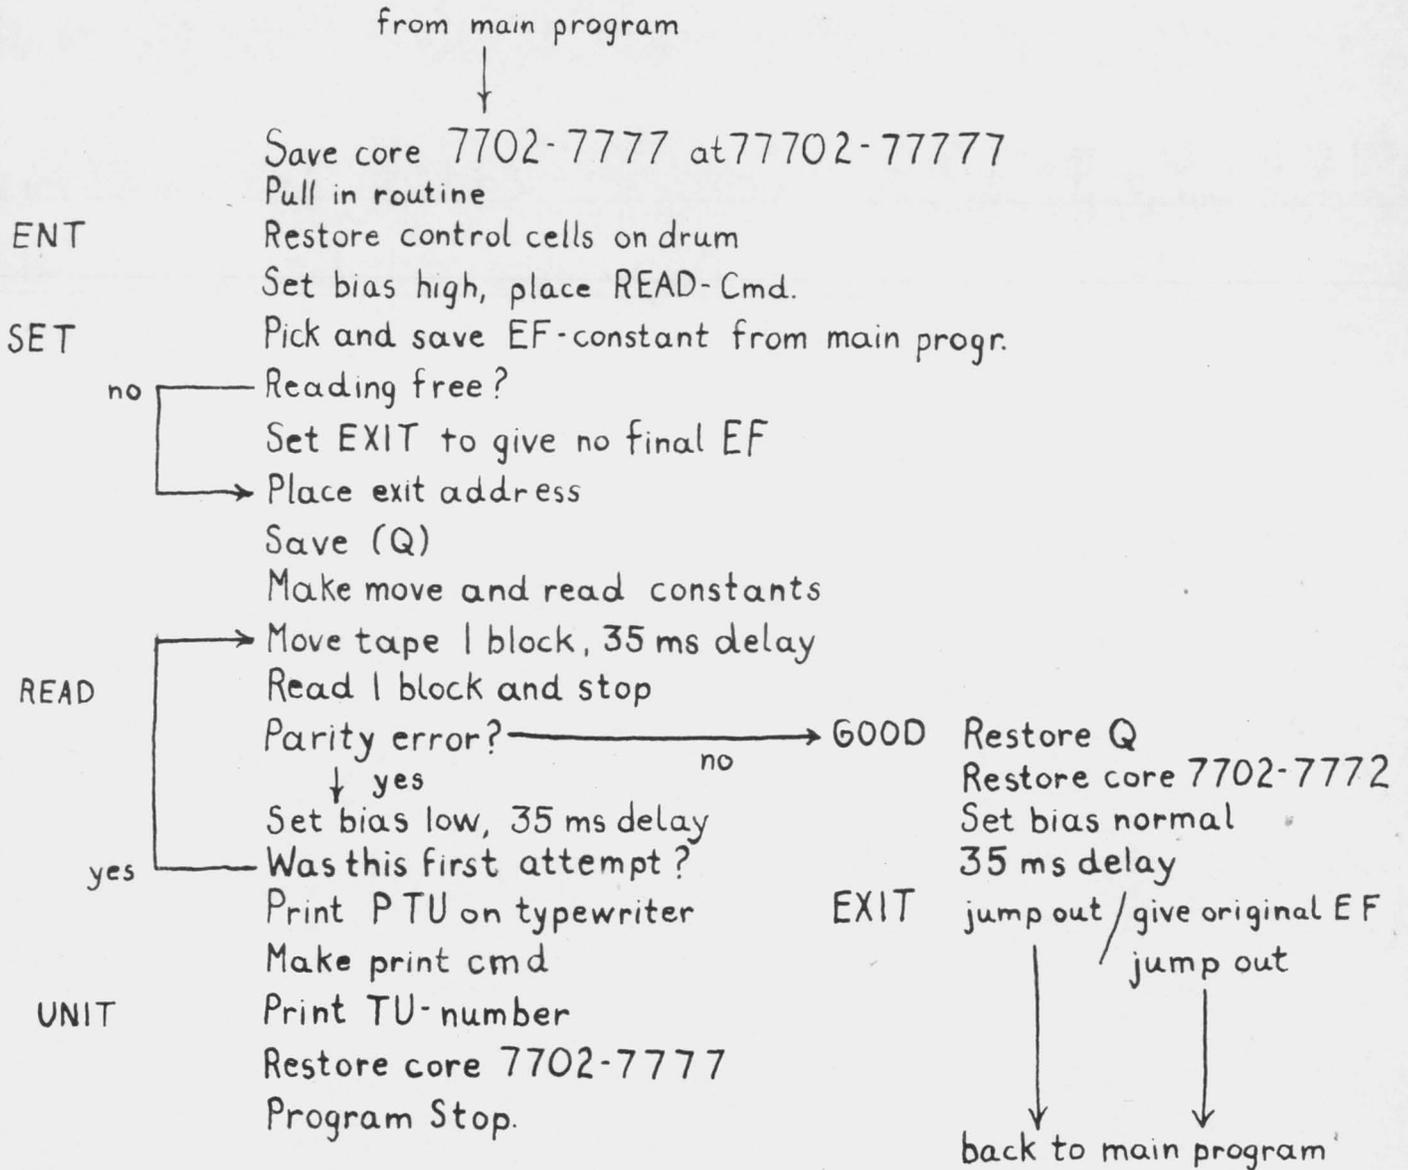

5. Restrictions

- a. Main program cannot use cells 07773-07777, and 77702-77777(image).
- b. Contents of Q is preserved, the main program may not read tape information into Q.
- c. Space needed in drum library = 62 cells. (HO-library 43610-43705)

BOEING 1103A SERVICE ROUTINE LIBRARY

GENERAL DESCRIPTION

During the course of program checkout the programmer often has need of information which is not normally supplied as a direct result of the operation of the program. The information required may be in a variety of forms and include such items as octal instructions, intermediate results in floating or stated point, contents of registers, or statements in English. It is expected that the programmers will provide for all foreseeable difficulties by programming linkages to standard subroutines to provide the required information. The diagnostic can be used in this fashion to provide listings of instructions in octal or direct statements regarding difficulties encountered. Output subroutines can be used to provide listings of intermediate results.

Because of the extremely large number of contingencies which might arise it is often impractical (if not impossible) for the programmer to provide for all such. This is particularly true of machine malfunctions. This Service Routine Library is made available to provide for such contingencies.

Included herein are the service routines most often required to provide the programmer with the information necessary to diagnose his difficulty and to assist the operator in the diagnosis of machine malfunctions. It should be noted that most of these routines are a simple rework of pre-existing routines to fit on the dead space of the Boeing 1103A computer. The routines were adapted from the Central Exchange Newsletters published by

BOEING 1103A SERVICE ROUTINE LIBRARY

GENERAL DESCRIPTION

Remington Rand or were taken from the customer engineers service routine library. Any or all of the service routines may be used by the programmer provided the operator is given a written set of instructions describing the routine to be used and how it is to be used.

The routines included in the library are packed with a 4 word interlace on the dead space of the drum where they cannot be inadvertently destroyed. Because of the limited space available the output of the routines is of the simplest form (octal instructions) and checking is kept to a minimum. Except as otherwise noted the routines are written to operate in the first part of core which is normally reserved for bootstrapping operations, the diagnostic and the tape read or write subprogram. The general procedure to initiate the use of a particular service routine is as follows:

1. Set Drum to ABNORMAL.
2. Set IAK equal to entry point of desired routine.
3. Press START key. Computer will stop at location which indicates successful transfer into core (or successful execution of the routine in the case of a routine which operates from the dead space).
4. Set Drum to NORMAL.
5. Enter parameters on console.
6. Turn on auxiliary equipment required (if any).
7. Press START key.

MAGNETIC TAPE BOOTSTRAP (VARIABLE BLOCK)

PURPOSE: Read the first block from magnetic tape on servo number 1 into magnetic core beginning with location 8(00240).

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40000.
3. Turn Uniservo #1 on.
4. Press START key. Computer will stop with PAK = 00240.
5. Set Drum to NORMAL.
6. Press START key to proceed.

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 42000 thru 42047 and 54040 thru 54047.
2. This routine works from MC locations 00000 thru 00044.

LIMITATIONS:

1. This routine assumes that the first block on magnetic tape was written in the variable block mode with an 18 bit check sum as the last word of the block.
2. This routine does not check for parity errors.

| | | | | | | |

| APPD | | | | | BOEING AIRPLANE COMPANY SEATTLE 14, WASHINGTON | PAGE |
| APPD | | | | | | 2.0 |

MAGNETIC TAPE BOOTSTRAP (VARIABLE BLOCK)

COMPUTER STOPS:

In the event that the reading of information from tape is incorrect as indicated by a check sum failure, this routine will attempt to re-read the information at high and low bias. In the event that the reading still fails to check the computer will stop with PAK = 00240 and MCT = 00034. In addition, the "low bias" status will be indicated. To ignore the check sum failure, set Drum to NORMAL and press the START key. To try reading again do a MASTER CLEAR and press the START key.

A successful reading of information from tape is indicated by the computer stopped with PAK = 00240 and MCT = 00035.

PAPER TAPE BOOTSTRAP

PURPOSE: Read a bi-octal paper tape into the addressable memory.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40001.
3. Press START key. Computer will stop with PAK = 00006.
4. Set Drum to NORMAL.
5. Turn on Ferranti Reader.
6. Press START key.

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 76000 thru 76044.
2. This routine works from MC locations 00000 thru 00044.

LIMITATIONS:

1. Information cannot be read from paper tape into MC locations 00000 thru 00044.
2. The following information must be punched in the tape in the order indicated.
 - a. Single seventh level punch.
 - b. Insert address (six frames with seventh level punch on third and sixth frames.

| | | | | | | |

| APPD | | | | | | |
| | | | | | BOEING AIRPLANE COMPANY SEATTLE 14, WASHINGTON | PAGE 3.0 |

PAPER TAPE BOOTSTRAP

LIMITATIONS: (contd.)

- c. Bi-octal computer words (six frames each with seventh level punch on sixth frame only - routine assumes frame immediately preceding first frame of word, i.e., last frame of preceding word, contained a seventh level punch).
 - d. Optional check address (a computer word with seventh level punch on fourth and sixth frames whose value is equal to the insert address plus the number of words read).
3. This program does not recognize the double seventh level punches used to indicate an end of tape and will continue to read tape until a FORCE STOP is executed from the console.
 4. The reading of information destined for magnetic core only can be accelerated slightly by setting switch MJ3 which suppresses the Ferranti stop after every sixth frame.

COMPUTER STOPS:

A check address failure is indicated by the execution of a PROGRAM STOP(57) command.

PAPER TAPE READ

PURPOSE: Read a bi-octal paper tape into the addressable memory.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40002.
3. Press START key. Computer will stop with PAK = 00011.
4. Set Drum to NORMAL.
5. Turn on Ferranti Reader.
6. Turn on Flexowriter.
7. Press START key.

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 46000 thru 46046
72000 thru 72037 and 74000 thru 74031.
2. This routine works from core locations 00000 thru 00137 and uses
locations 00140 thru 01777 as erasable storage.

LIMITATIONS:

1. Information cannot be read from paper tape into MC locations 00000
thru 01777.
2. The following information must be punched in the tape in the order
indicated.
 - a. Single seventh level punch.
 - b. Insert Address (six frames with seventh level punch on third
and sixth frames).

| | | | | | | | |
|----|---|------|------|---------|------|--------------------------------------|------------|

PAPER TAPE READ

LIMITATIONS: (contd.)

- c. Bi-octal computer words (six frames each with seventh level punch on sixth frame only - routine assumes frame immediately preceding first frame of word, i.e., last frame of preceding word, contained a seventh level punch).
 - d. Optional check address (a computer word with seventh level punches on fourth and sixth frames whose value is equal to the insert address plus the number of words read).
 - e. End of tape (2 seventh level punches in successive frames) following the last block on the tape.
3. A check sum may be used to check the reading of information. The check sum is formed by performing a repeated SA command and consists of two computer words. In the paper tape it must be preceded by an insert address of g(00272) and followed by a check address of g(00274). Where used it must be punched following the block of information and preceding the insert address for the next block.
4. A block of information punched in a tape without a check sum cannot be followed by a block for which a check sum is supplied. Each check sum encountered is used to check the reading of all information following the last check sum encountered or the beginning of the tape.

PAPER TAPE BLAD

COMPUTER STOPS:

1. A check address failure is indicated by the letter "C" typed on the flexowriter and PAK = 00040. To resume reading, press START key. To reread tape, set PAK = 00011.
2. A check sum failure is indicated by the letter "M" typed on the flexowriter and PAK = 00011. Press START key to resume reading or reread tape.
3. An end of tape is indicated by a computer stop with PAK = 45000.

FLEXOWRITER DUMP

PURPOSE: Print small blocks of instructions from the addressable memory in octal on the flexowriter. Since this is a relatively slow process, dumping with this program should be restricted to few instructions. In general, blocks of 8 instructions or more should be dumped with the octal dump (see next routine).

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40003.
3. Press START key. Computer will stop with PAK = 00020.
4. Set Drum to NORMAL.
5. Set location of first instruction to print in u-address of Q and number of instructions to print in v-address of Q.
6. Turn flexowriter on.
7. Press START key.

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 40042, 40043 and 70000 thru 70047.
2. This routine works from core locations 00000 thru 00047.

LIMITATIONS:

This routine will not print more than $8(1000) = 10^{(512)}$ words.

MAGNETIC TAPE DUMP

PURPOSE: Write instructions on magnetic tape in a form suitable for printing in octal on the High Speed Printer. Each page of instructions to be printed is preceded by a heading containing a fast feed symbol and a blank line. The instructions are printed 6 per line and 58 lines per page. A blank line containing a printer stop code follows the last instruction to print.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40004.
3. Press START key. Computer will stop with PAK = 00051.
4. Set Drum to NORMAL.
5. Set location of first instruction to print in u-address of Q and number of instructions to print in v-address of Q.
6. Turn Uniservo #2 on.
7. Press START key.

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 56000 thru 56045, 54000 thru 54037 and 66000 thru 66017.
2. This routine works from MC locations 00050 thru 00210.

LIMITATIONS:

The magnetic tape is written in variable block form one blockette of 20 words per record.

Q REGISTER TO MEMORY

PURPOSE: Transfer a word from the Q register to the addressable memory.
 Following the successful transfer, the word is displayed in the accumulator for checking.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40005.
3. Press START key. Computer will stop with PAK = 00001.
4. Set Drum to NORMAL.
5. Set location to store word in u-address and v-address of A right.
6. Enter word to store in Q register.
7. Press START key.
8. Word transferred will appear in A for checking.

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 40030 thru 40037.
2. This routine works from MC locations 00000 thru 00005.

LIMITATIONS: None

MEMORY TO Q REGISTER

PURPOSE: Display a word in the addressable memory for visual inspection.

The word to be displayed will appear in the Q register.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40006.
3. Press START key. Computer will stop with PAK = 00001.
4. Set Drum to NORMAL.
5. Set location of word to be displayed in the u-address of A right.
6. Press START key.
7. Word to be displayed will appear in the Q register.

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 40040, 40041 and 72044 thru 72047.
2. This routine works from MC locations 00000 thru 00003.

SET MEMORY TO ZERO

PURPOSE: Set all of magnetic core memory to zero. This routine works from the drum dead space.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40007.
3. Press START key. After clearing all of core memory, computer will stop with PAK = 40000.

STORAGE ASSIGNMENT:

This routine occupies "dead space" locations 60044 thru 60047 and works from these locations.

LIMITATIONS:

1. This routine assumes F1 (location 00000) contains a Manual Jump command prior to entering.
2. F1 is set to zero by this routine and must be restored before proceeding.

REWIND MAGNETIC TAPE.

PURPOSE: Rewind a magnetic tape from the console. This routine works from the drum dead space.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40010.
3. Press START key. Computer will stop with PAK = 40025 and (R) = 02 00200 00000.
4. Enter number of servo to be rewound in C₁₁ thru C₁₂.
5. Press START key to rewind tape.

STORAGE ASSIGNMENT:

This routine occupies "dead space" locations 40023 thru 40027 and works from these locations.

LIMITATIONS:

The servo number entered in C must be one of the logically assigned servos and must be ready.

COMPUTER STOPS: None.

RESTORE FI

PURPOSE: Restore the contents of FI (location 0000) to a Manual Jump command. The v-address portion of FI will not be altered.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set BAK = 40011.
3. Press START key. Computer will stop with BAK = 00000. The original contents of FI will be displayed in I.
4. Set Drum to NORMAL.
5. Press START key to transfer to FI and continue.

STORAGE ASSIGNMENT:

This routine occupies "dead space" locations 40044 thru 40047 and works from these locations.

LIMITATIONS: None.

31

BLOCK TRANSFER

PURPOSE: Transfer a block of consecutive words from one location to another within the addressable memory of the computer.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40012.
3. Press START key. Computer will stop with PAK = 00002.
4. Set Drum to NORMAL.
5. Set present starting address of block to be transferred in u-address of Q.
6. Set desired starting location of block in v-address of Q.
7. Set number of words to be transferred in u-address of A.
8. Press START key.

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 74040 thru 74047.
2. This routine works from core locations 00000 thru 00005.

LIMITATIONS:

All words to be transferred must be contained within the addressable memory both before and after transferring.

COMPUTER STOPS: None.

PAPER TAPE PUNCH (SI- CTAL)

PURPOSE: Punch a block of addressable memory into paper tape in bi-octal form. Insert and check addresses and a check sum are provided automatically but may be suppressed at the operator's option.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 40014.
3. Press START key. Computer will stop with PAK = 00006.
4. Set Drum to NORMAL.
5. Enter location of first word to punch in the u-address of Q and the number of words to be punched in the v-address of L.
6. Set MJ1 to suppress punching of insert and check addresses and check sum.
7. Set MJ2 to suppress punching check sum only.
8. Turn high speed punch on.
9. Press START key.

STORAGE ASSIGNMENT

1. This routine occupies "dead space" locations 60000 thru 60013 and 66020 thru 66016.
2. This routine works from core locations 00000 thru 00065 and uses locations 00272 and 00273 as erasable storage for the check sum.

LIMITATIONS: None

MAGNETIC TAPE BOOTSTRAP (FIXED BLOCK)

PURPOSE: Read the first block of 120 words from tape on servo #6 into MC locations 00001 thru 8(00170). This routine works from the drum dead space and was designed to bootstrap the customer engineers diagnostic routines.

ENTRY:

1. Set Drum to ABNORMAL.
2. Rewind tape on servo number 6.
3. Set PAK = 40016.
4. Press START key. After reading first block from tape 6 into core, computer will stop with PAK = 00116.
5. Set Drum to NORMAL.
6. Press START key to proceed.

STORAGE ASSIGNMENT:

This routine occupies "dead space" locations 74032 thru 74037 and works from these locations.

LIMITATIONS:

1. This routine assumes that the first block on tape 6 was written in fixed block form without blockette spaces.
2. This routine assumes F1 (location 00000) contains a Manual Jump (45) command. If F1 has been destroyed, restore F1 and start over.

TAPE TO TAPE CONVERSION

PURPOSE: Convert a magnetic tape containing binary information to a magnetic tape of a form suitable for printing the information on the High Speed Printer as octal instructions. The information is read from the tape to be converted into magnetic core beginning with location $8(01002)$. The record number is stored in location $8(01000)$ and the number of parity errors detected in reading that record is stored in location $8(01001)$. This information is written on the tape on servo #2 in XS3 code with 6 words per line and one blank line between each record. In addition, a trail is printed on the flexowriter to indicate the condition of each record as it is read from the tape.

ENTRY:

1. Set Drum to ABNORMAL.
2. Set PAK = 10020.
3. Press START key. Computer will stop with PAK = 00100.
4. Set Drum to NORMAL.
5. Set the servo number (n) containing the tape to be converted in Q_{11} thru Q_{12} .
6. Turn on servos number n and number 2.
7. Turn on flexowriter.
8. Set Switch MJI to suppress rewinding tape n before conversion.
9. Press START key.

TAPE TO TAPE CONVERSION

STORAGE ASSIGNMENT:

1. This routine occupies "dead space" locations 44000 thru 44047, 50000 thru 50047, 52000 thru 52047, 62000 thru 62047, and 64000 thru 64047.
2. This routine works from core locations 00000 thru 00423.

LIMITATIONS:

1. This program will not read records from tape containing more than $10(3582) = 8(6776)$ words.
2. Since servo #2 is used for output this program will not convert a tape on servo #2.

COMPUTER STOPS: None.

SUBJECT: Multiple Precision Floating Point Routine

CONTRIBUTOR: Remington Rand

A MULTIPLE PRECISION FLOATING POINT ROUTINE

FOR THE

UNIVAC SCIENTIFIC COMPUTER

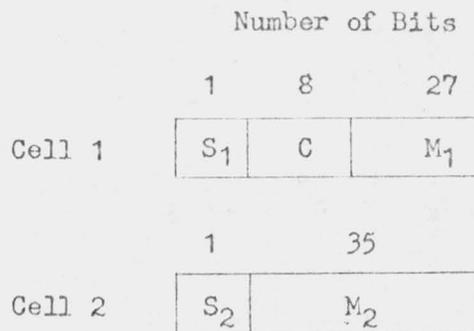

by
T. C. Tollefson

General Description

The multiple precision floating point routine, described on page 1 through 4, was coded for use with the Univac Scientific 1103A Computer. The coding is on pages 5 through 9 in both relative (RECO) and absolute addresses.

The routine performs arithmetic operations on floating point numbers of the order of 62 bits by use of stated point operations. Four arithmetic operations are provided by the routine; they are addition, subtraction, multiplication and division. Any one of the four operations may be performed by entering into the proper subroutine by means of the Interpret instruction. The Interpret instruction indicates the operation to be performed as well as the storage locations of the two operands involved.

Each of the two operands occupies two storage cells. The capacity of each cell or storage location is 36 bits and therefore each operand is 72 bits in length. For each operand, 62 bits are allocated for the mantissa M , 8 bits for the (biased) characteristic C , and 2 bits, S_1 and S_2 , for the sign. The 72 bits are arranged as shown below. The arrangement is true of both the operand and the result.

The higher order 27 bits (M_1) of the total 62 bits which comprise the mantissa are always in cell 1 and the lower order 35 bits (M_2) are always in cell 2. The mantissa contained in the two cells is always normalized and therefore the first significant bit occurs as the left-most bit of the higher order 27 bits, M_1 . The binary point is assumed to be immediately to the left of this bit (between C and M_1).

Any number N used by the routine must be in the form $M \cdot 2^C$ and must satisfy one of the following conditions

- (1) $N = 0$ or
- (2) $2^{-129} < |N| \leq 2^{127}$

The characteristic C is biased which allows the number N to vary over the values stated in (2) above. If K represents the normal exponent of the number, then C, the biased characteristic, is given by $C = K + 128$. The value of the mantissa M, located in M_1 and M_2 , may range in value as defined by the expression $\frac{1}{2} \leq M < 1$.

The sign bits S_1 and S_2 must be in agreement, that is, they must both be either zero or one. If they are "1's", M is a negative number and C and M are in one's complement form.

S_1 , S_2 , C, M_1 and M_2 are necessarily equal to zero whenever N equals zero.

The order of precision of this routine is 62 bits. The results are similarly 62 bits with an occasional round-off error at the 62nd bit.

The Interpret instruction 14 OP U'V' is utilized to initiate any one of the arithmetic operations. The operation code, OP, used for any specific operation is analogous to the regular machine codes for standard stated point operations. The code for these four arithmetic operations is listed below.

| | |
|-----------|---------|
| Add: | AT (35) |
| Subtract: | ST (36) |
| Multiply | MP (74) |
| Divide: | DV (73) |

The U' and V' addresses refer to the first of two consecutive storage locations at which each operand is stored. Thus, if the first operand is stored at u_1 and u_2 , and the second operand at v_1 and v_2 ; $U' = u_1$ and $V' = v_1$.

The result of the operation performed is properly packed and normalized and is found in the A and Q registers. The result containing the higher order 27 bits and the characteristic, is in double extension form in A. At the conclusion of the operation (i.e., control transferred to F_1), the initial operands are found undisturbed in their original locations U' , and $U' + 1$, and V' , $V' + 1$.

The coding of the routine, pages 5 through 9, is in two forms; the address in the left-hand column is relative to 1000, and the right-hand code is in RECO form.

The routine is divided into six subroutines, ready for RECO assembly. The regional assignments are given below.

SA: addition and subtraction
MP: multiplication
DV: division
DC: decoder and unpacking
RP: rounding and packing
CS: constants and temporary storage

A jump instruction at F_2 transfers control to 1000 (DCO), which initiates decoding, i.e., determines which arithmetic operation is to be performed, and unpacks the normalized, packed operands. DCO is the absolute location of the first instruction of the decoding section. A jump is then made to the desired subroutine (SA, MP, DV) to perform the arithmetic operation. The rounding and packing subroutine (RP) performs a rounding operation and truncation at the 63rd bit of the mantissa and normalizes and packs the results which are then stored in A and Q. Control is now transferred to F_1 , which contains a jump instruction to the address following the initiating Interpret instruction.

Use of the Routine

If the six subroutines discussed above are to be RECO assembled, the individual subroutine regions must be labeled SA, MP, DV, DC, RP and CS. These may be placed, individually, anywhere in the memory that is desired; or, the entire routine, coded relative to 1000, may be address-modified to be placed as one package anywhere in the memory.

The routine does not set up F_1 or F_2 ; these must be preset by the user and should be set up as follows:

F_1 : MJ 0 [0]
 F_2 : MJ 0 1000 (or DCO)

The Interpret instruction modifies the v address of F_1 ; F_1 and F_2 are not modified in any way by the routine.

If we let U' and V' represent the storage of the two operands, these each being separated into two locations, u_1, u_2 and v_1, v_2 it must be remembered that u_1 and u_2 must be consecutive as are v_1 and v_2 . U' and V' need not be consecutive.

Example:

Compute $(a - b)$: a is stored at 00500 and 00501, and b at 02100 and 02101. The proper Interpret instruction would be 1436 0500 2100. Note: Drum addresses cannot be used.

Alarm and Excess Considerations

The characteristic C, equal to $K + 128$ as stated above, cannot exceed certain limits. Results which yield biased characteristics greater than 255 or less than zero cannot be expressed; consequently, alarms and/or procedures have been incorporated in the routine to indicate when these limits have been exceeded.

If the characteristic of the result is $C \leq 0$ or $C > 255$, zeros are entered in the result locations and control transferred to F_1 . If instead of having zeros entered into the result and control transferred to F_1 , it is desired to have an alarm or error exit under these extremes, two instructions, 1203 (RP52) and 1212 (RP61), must be changed. These two instructions normally read

RP52 : MJ O RP55

RP61 : SJ RP55 RP53

These must be altered to read

RP52 : MJ O C

RP61 : SJ C RP53,

where C is any specified (by the user) cell to jump to in case of the above extreme condition. Note: If it is convenient to have results equal to zero in case the characteristic C becomes less than zero and have an alarm only for $C > 255$, RP52 is the only cell that need be altered.

If an attempt is made to divide by zero the operation is by-passed, control is transferred back to F_1 , but the computer is halted by the instruction DV51, which normally reads MS O O. This instruction may be altered to provide any needed divide-error indication or exit.

Since no check is made on the validity (correctness of format) of the input operands, use of incorrect operands will result in either an error indication or nonsensical answers.
